Abstract—Interpolating, i.e., computing safe over-approximations for a system represented by a logical formula, is at the core of symbolic model-checking. One of the central tools in modeling programs is the use of the equality logic and uninterpreted functions (EUF), but certain aspects of its interpolation, such as size and the logical strength, are still relatively little studied. In this paper we present a solid framework for building compact, strength-controlled interpolants, prove its strength and size properties on EUF, implement and combine it with a propositional interpolation system and integrate the implementation into a model checker. We report encouraging results on using the interpolants both in a controlled setting and in the model checker. Based on the experimentation the presented techniques have potentially a big impact on the final interpolant size and the number of counter-example-guided refinements.

I. INTRODUCTION

An important skill in constructing mathematical proofs is to identify the aspects of the problem that are relevant. When applied to formal reasoning about the correctness of software this means ignoring the parts of the system that play no role in its correctness. One such approach that works well in automated software verification based on satisfiability modulo theories (SMT) engines (see, e.g. [1]) is to employ the Equality Logic and Uninterpreted Functions (EUF) when applicable: in some cases it suffices to assume that a given function returns the same value when invoked with the same arguments. This technique is particularly useful, for example, when modeling memory or arrays [2], proving program equivalence [3], or as a technique for avoiding flattening in solving bit-vector problems [4], [5].

Generalizing a formula over the states reachable by a program is a natural subtask when summarizing the behavior of a procedure [6], or computing a fixed-point of a transition function [7], [8]. These techniques are now popular in software model-checking [9], [10], and together with the theory-based abstraction result in a growing interest in an overapproximation technique known as interpolation.

In this paper we present the EUF-interpolation system which aims at specializing and tailoring interpolants for the needs of interpolation-based model-checking. The paper contributes to the state-of-the-art by (i) providing the first approach for controlling the strengths of EUF interpolants; (ii) identifying a strength lattice of interpolation algorithms; and (iii) proving under certain assumptions the size order for the interpolants produced by the system. In addition we (iv) provide an implementation of the system; (v) integrate and experiment with the system on a model checker; and (vi) study the combination of labeled interpolation systems for EUF and propositional logic. The EUF-interpolation operates on the proof of unsatisfiability in EUF based on a recursive algorithm for building a final interpolant from partial interpolants and uses duality of interpolants, a logical relation between an interpolant and its negation discussed below, to control the strength of the constructed partial and final interpolants.

The system is implemented in the SMT solver OpenSMT2 [11], and used in a model-checking algorithm based on the interpolating incremental C verifier HiFrog [6]. This gives us the advantage of making a direct connection between the theoretical contributions and practice. We evaluate the efficiency of the EUF-interpolation system with two major experiments. In the first experiment we verify a set of C software verification problems produced by HiFrog, and in the second experiment we study different combinations of propositional and EUF interpolation algorithms on a set of instances from the SMT-LIB benchmark collection. Based on the results the system has a big impact on the generated interpolants, and the interpolants seem to be very useful in our application to model-checking. To the best of our knowledge our work is the first to consider the duality of interpolants in constructing EUF interpolants recursively, and to report experiments with EUF interpolation together with incremental verification.

a) Related work: Recent work on labeled interpolation systems (LIS) addresses interpolation in propositional logic [12], [13], [14], [15] by providing control over fitting the interpolant strength and size to particular model-checking applications. Our approach extends the work on propositional interpolation to SMT theories and in particular to EUF. Interpolation procedures for EUF have been introduced in [16], [17]. The interpolation procedure given in [16] provides a way of computing a single interpolant from a given proof. The technique is extended in [17] to allow construction of several interpolants through the coloring of congruence graphs edges. Our work differs fundamentally from both these approaches by using duality for controlling the interpolant strength, a feature not available in earlier formalizations.

The parametric interpolation frameworks presented in [18] and [19] generalize first-order interpolation procedures. The former provides labeled interpolation systems for hyper-resolution proofs which are then extended to first order in-
terpolation systems for local proofs; the latter generalizes the former further to non-local proofs. Both of these techniques provide control on the propositional level. Unlike ours, they are not specialized and optimized for EUF and, to the best of our knowledge, have not been implemented.

Other orthogonal procedures exist for the quantifier-free fragments of the theories of linear integer arithmetics [20], [21], linear real arithmetics [16], [22], [23], and Arrays [24], while [25] provides a labeled interpolation system for Non-linear Real Arithmetics. On a high level, we believe that the duality-based approach followed in this work can be applied also in these fields.

This paper is organized as follows: Sec. II presents a general algorithmic framework for interpolation as a preliminary for the EUF-interpolation system. The main result on the EUF-interpolation system is presented in Sec. III The experiments are reported in Sec. IV, and the paper concludes in Sec. V. For lack of space we present most of the proofs of the theorems in Appendix A. The implementation and more experimental results are available at http://verify.inf.usi.ch/euf-interpolation.

II. PRELIMINARIES

This paper considers the extension of propositional logic to Boolean variables that are interpreted as equalities over uninterpreted functions. Following [26], we call the extension the theory of equality logic and uninterpreted functions (EUF). For example, \( \neg(a = b) \lor f(a) = f(b) \) is an EUF formula containing the uninterpreted functions \( a, b \), and \( f \), embedded in a Boolean structure. Given an EUF formula \( F \), we call the equality (=), and the Boolean connectives (e.g., \( \neg, \land, \lor \)) the logical symbols, while the Boolean variables and uninterpreted functions are its non-logical symbols, denoted by \( \mathit{Vars}(F) \).

Given an unsatisfiable conjunction \( A \land B \) of EUF formulas \( A \) and \( B \), an interpolation instance is a pair \( (A, B) \), and an interpolant for \( (A, B) \) is a formula \( I(A, B) \) such that (i) \( A \rightarrow I(A, B) \), (ii) \( I(A, B) \land B \) is unsatisfiable, and (iii) \( \mathit{Vars}(I(A, B)) \subseteq \mathit{Vars}(A) \cap \mathit{Vars}(B) \). In general several interpolants can be computed for an instance \( (A, B) \). We denote an algorithm computing an interpolant \( I(A, B) \) by \( \mathit{Itp}(A, B) \), and, with a slight abuse of the notation, use \( \mathit{Itp}(A, B) \) to denote the interpolant \( I(A, B) \) when the interpolation algorithm needs to be specified. A concept central to this paper is the duality between interpolation algorithms:

Given an interpolation algorithm \( \mathit{Itp}(A, B) \), also the algorithm \( \mathit{Itp}^\neg(A, B) \) returning \( \neg \mathit{Itp}(B, A) \) computes an interpolant for \( (A, B) \), as can be seen from the following reasoning: By definition, \( \mathit{Itp}^\neg(A, B) = \neg \mathit{Itp}(B, A) \). \( \mathit{Itp}(B, A) \) satisfies (i) \( B \rightarrow \mathit{Itp}(B, A) \); (ii) \( \mathit{Itp}(B, A) \rightarrow \neg A \); and (iii) \( \mathit{Vars}(\mathit{Itp}(B, A)) \subseteq \mathit{Vars}(A) \cap \mathit{Vars}(B) \). By rewriting, from (ii) follows that (iv) \( A \rightarrow \neg \mathit{Itp}(B, A) \), and from (i) that (v) \( \neg \mathit{Itp}(B, A) \rightarrow B \). From (iii), commutativity of intersection, and definition of non-logical symbols, follows (vi) \( \mathit{Vars}(\neg \mathit{Itp}(B, A)) \subseteq \mathit{Vars}(B) \cap \mathit{Vars}(A) \).

In this work we consider algorithms that build interpolants based on the unsatisfiability proof of \( A \land B \). We make this explicit by denoting the interpolation algorithm (and the resulting interpolant) by \( \mathit{Itp}(A, B, R) \), where \( R \) is the refutation representing the proof of unsatisfiability. In this work we are particularly interested in ordering interpolation algorithms with respect to the strength of the interpolants they compute. An interpolant \( I \) is stronger than an interpolant \( I' \) if \( I \rightarrow I' \). We extend the strength relation to interpolation algorithms: if \( \mathit{Itp}^* (A, B, R) \rightarrow \mathit{Itp}^w (A, B, R) \) for algorithms \( \mathit{Itp}^* \) and \( \mathit{Itp}^w \) for all interpolation instances \( (A, B) \) with a fixed refutation \( R \) for \( A \land B \), then \( \mathit{Itp}^* \) is stronger than \( \mathit{Itp}^w \). If the strength relation can be established between the algorithms \( \mathit{Itp} \) and \( \mathit{Itp}' \), we call the algorithm computing the stronger interpolant the base and the weaker the dual interpolation algorithm and denote them by \( \mathit{Itp} \) and \( \mathit{Itp}' \), respectively.

A. EUF Preliminaries

This section describes our interpolation system for EUF. The presentation is based on [17] and uses the congruence graph as the refutation.

Many EUF solvers rely on the congruence closure algorithm [27] to decide the satisfiability of a set of equalities and disequalities. The algorithm, described in Alg. 1, takes as input a finite set \( \mathit{Eq} \) of equalities, and the set \( T \) of subterm-closed terms over which \( \mathit{Eq} \) is defined. During the execution the algorithm builds an undirected congruence graph \( G \) using the set \( T \) as nodes. We write \( (x \sim y) \) if there is a path in \( G \) connecting \( x \) and \( y \) and denote this path by \( \pi \).

**Theorem 1** (c.f. [27]): Let \( S \) be a set of EUF disequalities \( x \neq y \) over the terms \( T \). The set \( S \cup \mathit{Eq} \) is satisfiable if and only if the congruence graph \( G \) constructed by \( \mathit{CONGRUENCECLOSURE}(T, \mathit{Eq}) \) has no path \((x \sim y)\) such that \((x \neq y) \in S\).

During the creation of \( G \), an edge \((x, y)\) is added only if \((x \sim y)\) does not hold, which ensures that \( G \) is acyclic. Therefore, for any pair of terms \( x \) and \( y \) such that \((x \sim y)\) holds in \( G \), the path \( \pi \) connecting these terms is unique. Empty paths are represented by \( \pi \). For an arbitrary path \( \pi \), we use the notation \([\pi] \) to represent the equality of the terms that \( \pi \) connects. If, for example, \( \pi = \pi \), then \([\pi] := (x = y) \). We also extend this notation over sets of paths \( P \) so that \([P] : = \bigwedge_{\pi \in P}[\pi] \).

An edge may be added to a congruence graph \( G \) because of two different reasons in Alg. 1 at line 7. Edges added because of Condition (a) are called basic, while edges added because of Condition (b) are called derived. Let \( e \) be a derived edge.
A coloring $C$ of a congruence graph $G = (E,T)$ created over the equalities and terms of $A \cup B$ is a function $C : E \to \{a,b\}$, that is, $C$ assigns a color $a$ or $b$ to each edge, considering two restrictions: (i) basic edges $e$ must be colored with $a$ if $e \in A$ and with $b$ if $e \in B$; and (ii) if an edge has color $\kappa \in \{a,b\}$, both its endpoints must be $\kappa$-colorable. a-colorable derived edges can be colored arbitrarily. To compute the interpolant the congruence graph needs to be annotated with the information on which equalities and formulas belong to which partition. Equalities and formulas are a-colorable if all their non-logical symbols occur in $A$, and b-colorable if all their non-logical symbols occur in $B$. They are colorable if they are $a$ or $b$-colorable, and ab-colorable if both. An edge $(x, y)$ of a congruence graph has the same color as the equality $(x = y)$. A path in a congruence graph is colorable if all its edges are colorable, and a congruence graph is colorable if all its edges are colorable.

While it is possible to construct a non-colorable congruence graph, the following lemma and its constructive proof in [17] state that we may assume without loss of generality that congruence graphs are colorable.

**Lemma 1** (c.f. [17]): Let $(A, B)$ be an interpolation instance over EUF. If $x$ and $y$ are colorable terms and if $A, B \models (x = y)$, then there exist a term set $T$ and a colorable congruence graph over the equalities contained in $A \cup B \cup T$ in which $(x \sim y)$.

We denote a congruence graph $G$ colored with a function $C$ by $G^C$. A path is called an $a$-path if all its edges are colored $a$, and a $b$-path if all its edges are colored $b$. A factor of a path in $G^C$ is a maximal subpath such that all its edges have the same color. Notice that every path is uniquely represented as a concatenation of the consecutive factors of opposite colors.

**Example 1:** Let $A := \{ (v_1 = f(y_1)), (f(y_2) = v_2), (y_1 = t_1), (t_2 = y_2), (s_1 = f(r_1)), (f(r_2) = s_2), (r_1 = u_1), (u_2 = r_2) \}$ and $B := \{ (x_1 = v_1), (v_2 = x_2), (t_1 = f(z_1)), (f(z_2) = t_2), (z_1 = s_1), (s_2 = z_2), (u_1 = u_2), (x_1 \neq x_2) \}$. Figure 1 shows a colored congruence graph $G^C$ built while proving the unsatisfiability of $A$ and $B$ with Alg. 1. The curvy edges with the labels $s$ or $w$ in $G^C$ are not relevant for this example and are used later in Section III. The congruence graph $G^C$ demonstrates the joint unsatisfiability of $A$ and $B$, since it proves $(x_1 = x_2)$ and $(x_1 \neq x_2)$ is an original term. Edges are represented by thick lines, and dotted arrows point to the parents of derived edges. We present a-colorable nodes (terms) and a-colored edges by black circles and solid lines, b-colorable nodes and b-colored edges by white circles and dashed lines, and ab-colorable nodes by gray circles. In the first (top) path of $G^C$, we see that basic edges (original equalities from $A \cup B$) are used to prove $(r_1 = r_2)$. This fact is used to infer $(f(r_1) = f(r_2))$, which is in turn used as a derived edge in the path below, proving $(z_1 = z_2)$. The equality $(f(z_1) = f(z_2))$ is then inferred and used to prove $(y_1 = y_2)$ in the path below. In the last (bottom) path of $G^C$, the derived edge representing $(f(y_1) = f(y_2))$ is created and finally $(x_1 = x_2)$ is proved.

### III. The EUF Interpolation System

In this section we present the EUF-interpolation system which extends the approach described in [17] with a modular use of dual interpolants. The main novelty of the system the control over the interpolant strength. Due to lack of space all the proofs of the theorems in this section are presented in Appendix A.

Intuitively, the approach computes partial interpolants with either a base or a dual interpolation algorithm using the structure of a congruence graph. We show that while interpolating on a fixed congruence graph the liberty in choosing between the two interpolation algorithms allows computing several interpolants that can be partially or fully ordered with respect to their strength. To make this choice explicit we introduce the labeling functions $L$ for the EUF-interpolation interpolation system, and the algorithm $Itp_L$ for computing the interpolants.

**Definition 1** (Labeling function): Let $G[\overline{x}]^C$ be a colored congruence graph and $W$ its factors. A labeling function $L : W \cup \{\overline{x}\} \rightarrow \{s, w\}$ labels the factors and the path corresponding to the conflict $x \neq y$ as $s$ or $w$.

We want to emphasize that colors, described in Sec. II-A, and labels are different concepts. The colors $a, b$ tell if a node or edge in a congruence graph belongs to $A$ or $B$, whereas labels $s, w$ are used while deciding whether to use the standard or the dual interpolant.

Given an (unsatisfiable) interpolation instance $(A, B)$, an EUF interpolation algorithm $Itp_L(A, B, G[\overline{x}]^C)$ computes an interpolant for $(A, B)$; $G[\overline{x}]^C$ is a congruence graph with coloring $C$; $\overline{x}$ a path such that $(x \sim y)$ is in $G$ and the inequality $(x \neq y)$ exists in $A \cup B$; and $L$ is a labeling function. We omit $A, B, G^C$ and $L$ when they are clear from the context, referring to the interpolation algorithm and the corresponding interpolant as $Itp_L(\overline{x})$. We define separately two constant labeling functions $L_s(\sigma) = L_w = s$ and $L_w(\sigma) = L_w = w$ that will be useful in the following analysis.

The interpolation algorithms in [16] and [17] essentially compute an interpolant by collecting the $A$-factors that prove $(x = y)$ in $G^C$. To maintain the unsatisfiability with the $B$
part of the problem, the \( A \) factors will then be implied by their \( B \)-premise set. A premise set for a color is the set of equalities of the opposite color justifying the existence of a parent edge. More technically, the \( B \)-premise set \( B \) for a path \( \pi \) is

\[
B(\pi) := \begin{cases} 
\{ \{ \}, \} & \text{if } \pi \text{ has } \geq 2 \text{ factors}; \\
\{ \{ \}, \} & \text{if } \pi \text{ is a } B\text{-path}; \\
\{ \{ \}, \} & \text{if } \pi \text{ is an } A\text{-path}. 
\end{cases}
\]

As stated in Sec. II, it is also possible to compute a dual interpolant for \( A \) as the negation of an interpolant for \( B \). To compute the dual interpolant we will need similarly to collect the \( B \)-factors that prove \( (x = y) \) in \( G' \), implied by their \( A \)-premise set. The \( A \)-premise set \( A \) for a path \( \pi \) is defined as

\[
A(\pi) := \begin{cases} 
\{ \{ \}, \} & \text{if } \pi \text{ has } \geq 2 \text{ factors}; \\
\{ \{ \}, \} & \text{if } \pi \text{ is an } A\text{-path}; \\
\{ \{ \}, \} & \text{if } \pi \text{ is a } B\text{-path}. 
\end{cases}
\]

We extend the notation of \( A \) and \( B \) over a set \( S \) of paths as

\[
A(S) := \bigcup_{\pi \in S} A(\pi) \quad \text{and} \quad B(S) := \bigcup_{\pi \in S} B(\pi).
\]

For any two operators \( O, O' \) such that domain of \( O \) contains the range of \( O' \) we define the composite operator \( O'O'(\sigma) := O(O'(\sigma)) \) and define recursively \( O^n(\sigma) := \sigma \), and \( O^n := O(O^{n-1}) \).

The functions \( J_A \) and \( J_B \) give, respectively, the contribution of an individual \( A \)-factor and an individual \( B \)-factor to the interpolants.

\[
J_A(\pi) := [B(\pi)] \to [\pi] \quad \text{(3)} \\
J_B(\pi) := [A(\pi)] \to [\pi] \quad \text{(4)}
\]

Let \( S \) be a set of paths. The notation \( S|_{\nu} \) represents the subset of \( S \) containing the paths \( \sigma \) such that \( L(\sigma) = \nu \) for \( \nu \in \{ s, w \} \). Let \( (A, B) \) be an EUF interpolation instance, \( G \) the corresponding congruence graph, and \( x \neq y \in A \cup B \) that is in conflict with \( G \). Let \( P = (A, B, G[\pi_y]) \). The algorithm \( I_{\nu} \) computes the EUF interpolant over \( A \) for a path \( \pi_y \).

It is defined using four sub-procedures \( I_A, I'_A, I_B, \) and \( I'_B \) that map congruence graphs to partial interpolants, and are invoked depending on which partition the conflict \( x \neq y \) belongs to and what label the path \( \pi_y \) has:

\[
I_{\nu}(\pi_y) := \begin{cases} 
I_A(\pi_y) & \text{if } (x \neq y) \in B \land L(\pi_y) = s, \\
I'_A(\pi_y) & \text{if } (x \neq y) \in A \land L(\pi_y) = s, \\
-I_B(\pi_y) & \text{if } (x \neq y) \in A \land L(\pi_y) = w, \text{ and} \\
-I'_B(\pi_y) & \text{if } (x \neq y) \in B \land L(\pi_y) = w. 
\end{cases}
\]

The sub-procedures for \( I_A \) and \( I_B \) are defined as

\[
I_A(\pi) := \bigwedge_{\sigma \in A(\pi)} J_A(\sigma) \quad \bigwedge_{\sigma \in B(\pi)} I_A(\sigma) \quad \bigwedge_{\sigma \in B(\pi)} \neg I_B(\sigma). \quad \text{(6)}
\]

For the cases where either the conflict \( x \neq y \in A \land L(\pi_y) = s \), or the conflict \( x \neq y \in B \land L(\pi_y) = w \), the path \( \pi_y = \pi \) needs to be decomposed for computing the partial interpolant as \( \pi = \pi_1 \theta_1 \pi_2 \) or \( \pi_1 \theta_2 \pi_2 \), where \( \theta_\pi \) is the longest subpath of \( \pi \) with \( \kappa \)-colorable endpoints. Hence, \( I_A \) and \( I'_A \)

\[
I_A(\pi) := I_A(\theta_1) \bigwedge_{\sigma \in B(\pi_1) \cup B(\pi_2)} I_A(\sigma) \quad \bigwedge_{\sigma \in B(\pi_1) \cup B(\pi_2)} \neg I_A(\sigma). \quad \text{(8)}
\]

and

\[
I'_A(\pi) := I_A(\theta_1) \bigwedge_{\sigma \in B(\pi_1) \cup B(\pi_2)} I_A(\sigma) \quad \bigwedge_{\sigma \in B(\pi_1) \cup B(\pi_2)} \neg I_A(\sigma). \quad \text{(9)}
\]

Theorem 2: Given two sets of equalities and disequalities \( A \) and \( B \) such that \( A \cup B \) is unsatisfiable, a colored congruence graph \( G' \) containing a path \( \pi := \pi_y \) such that \( (x \neq y) \in A \cup B \), and a labeling function \( L \), Eq. (5) computes a valid interpolant for \( A \) using \( L \) over \( G' \).

The following example shows how Eq. (5) can be used to compute the interpolants from [17].

Example 2: Let \( A := \{ (x_1 = f(x_2), (f(x_3) = x_4), (x_4 = f(x_5), (f(x_6) = x_7) \} \) and \( B := \{ (x_2 = x_3, (x_5 = x_6, (x_1 \neq x_7) \} \). Figure 2 shows a possible congruence graph \( G' \) that proves the joint unsatisfiability of \( A \) and \( B \) (by proving \( (x_1 = x_7) \) such that \( (x_1 \neq x_7) \in A \cup B \)) and its tree representation, with each node annotated by its partial interpolant. In this example we use the constant labeling function \( L_s = s \). From Eq. (5) we have that \( I_{\nu}(\pi_{x_1}) = I_A(\pi_{x_1}) \) because \( L_A(\pi_{x_1}) = s \) and \( (x_1 \neq x_7) \in B \). The call to \( I_A(\pi_{x_1}) \) is represented by the root node in the tree in Figure 2. First we compute \( I_A(\pi_{x_1}) = \{ \pi_{x_1} \} \) and \( I_A(\pi_{x_2}) = \{ \pi_{x_2} \} \). Then from Eq. (6) we have that \( I_A(\pi_{x_1}) = I_A(\pi_{x_2}) \) and \( I_A(\pi_{x_3}) \) are represented by the edges from the leaf nodes to the root in the tree in Figure 2. We then proceed computing \( A(\pi_{x_2}) = \emptyset \) and \( B(\pi_{x_2}) = \emptyset \) which lead to \( I_A(\pi_{x_2}) = \emptyset \); and \( A(\pi_{x_3}) = \emptyset \) and \( B(\pi_{x_3}) = \emptyset \) which lead to \( I_A(\pi_{x_3}) = \emptyset \) (the partial interpolants of the leaf nodes). Finally, we have that \( I_A(\pi_{x_1}) = (x_2 = x_3) \land (x_5 = x_6) \) is the partial interpolant of the root node, \( (x_1 = x_7) \) is the partial interpolant of the root node, representing the final interpolant for \( A \).

A. The Interpolant Strength
Let \( P = (A, B, G[\pi_y]) \) and \( L_s \) and \( L_w \) the weak and the strong labeling functions. We will show in Th. 3 that \( I_{\nu}(\pi) \to I_{\nu}(\pi_y)(P) \) and then in Ex. 3 that there are cases where the strength relation is strict in the sense that there are models that satisfy \( I_{\nu}(\pi) \) but do not satisfy \( I_{\nu}(\pi_y)(P) \). Theorem 3 needs Lemma 4 which in turn is a generalization of Lemma 2. We then show our main result on EUF in Theorem 4, that is, we provide a way to compare
functions the interpolants generated by Eq. (5) by using the labeling functions.

**Lemma 2:** Let $G^C$ be a congruence graph with coloring $C$, and $\omega$ a factor from $G$. Then $I_A(\omega) \land I_B(\omega) \rightarrow [\omega]$.

**Lemma 3:** Let $\pi$ be an arbitrary path in the congruence graph, and $\phi(\pi)$ the set of all factors in $\pi$. Then $I_A(\pi) = \bigwedge_{\sigma \in \phi(\pi)} I_A(\sigma)$ and $I_B(\pi) = \bigwedge_{\sigma \in \phi(\pi)} I_B(\sigma)$.

**Lemma 4:** Lemma 2 holds when $\omega$ is a path containing multiple factors.

**Theorem 3:** For fixed $A, B,$ and $G[\prod y]$, for the corresponding interpolants defined in Eq. (5) it holds that $Itp_{L_a}(A, B, G[\prod y]) \rightarrow Itp_{L_b}(A, B, G[\prod y])$.

To show that the implication is not trivial in general, we show by example that three different labeling functions being applied to the congruence graph from Ex. 1 result in three pairwise inequal interpolants.

**Example 3:** Consider again the sets $A$ and $B$ and the congruence graph $G^C$ from Ex. 1 and Fig. 1. Let $L_c$ be a custom labeling function mapping the paths to labels as $\{x_1x_2 \mapsto s, x_1x_2x_3 \mapsto s, x_1x_2x_3x_4 \mapsto s, x_1x_2x_3x_4x_5 \mapsto w, x_1x_2x_3x_4x_5x_6 \mapsto w, x_1x_2x_3x_4x_5x_6x_7 \mapsto w\}$. We recall that the labeling function only needs to be defined on the factors and the path that contradicts the original disequality, in this case $x_1x_2$. The labels are shown over curves representing which path is labeled. The labeling function $L_c$ represents the intent of generating stronger partial interpolants closer to $(x_1 = x_2)$, and weaker partial interpolants in the inner explanations. Let $Itp_s$, $Itp_w$, and $Itp_c$, be, respectively, the interpolants generated by Eq. (5) by using the labeling functions $L_s$, $L_w$, and $L_c$. The computed interpolants are $Itp_s = \{((t_1 = t_2) \rightarrow (v_1 = v_2)) \land ((u_1 = u_2) \rightarrow (s_1 = s_2))\}$, $Itp_w = \neg((u_1 = u_2) \land ((s_1 = s_2) \rightarrow (t_1 = t_2)) \land \neg(v_1 = v_2))$, and $Itp_c = ((t_1 = t_2) \rightarrow (v_1 = v_2)) \land \neg(((s_1 = s_2) \rightarrow (t_1 = t_2)) \land (u_1 = u_2)) \land \neg((t_1 = t_2))$. The reader is welcome to verify that $Itp_s \rightarrow Itp_c \rightarrow Itp_w$, and none of them is equivalent to another.

Finally we present our main result providing a way to partially order interpolation algorithms into a lattice based on their strength. From this follows that the constant labeling functions $L_s$ and $L_c$ give, respectively, the strongest and the weakest interpolants within this framework.

**Theorem 4:** Let $\sqsupseteq$ be a strength relation defined over the labels $s$ and $w$ such that $s \sqsupseteq s$, $w \sqsupseteq w$ and $s \sqsupseteq w$. Let $(A, B)$ be an interpolation instance, $G^C$ a congruence graph proving the unsatisfiability of $A \land B$, and $L$ and $L'$ two labeling functions such that $L(\sigma) \sqsubseteq L'(\sigma)$ for all the factors $\sigma$ of $G^C$. Then $Itp_L(A, B, G^C) \rightarrow Itp_{L'}(A, B, G^C)$.

### B. Interpolant Size

The EUF-interpolation system presented above introduces a way of computing interpolants of different strength by labeling the factors of a congruence graph as $s$ or $w$, depending on the required strength. Each labeling function results potentially in a different interpolant, and creating meaningful labeling functions is a challenging task on its own. For the labeling functions $L_s$ and $L_w$ we give the following results with respect to their size.

**Theorem 5:** Let $P = (A, B, G^C)$. The interpolant with the smallest number of equalities over all interpolants computable with the EUF interpolation system is $Itp_{L_s}(P)$ if $\pi \in B$ and $Itp_{L_w}(P)$ if $\pi \in A$.

The EUF interpolation system presented in this section provides a rich platform that allows the adjustment of interpolants to particular tasks. In the following we will study how the approach works in practice.

### IV. Experiments

We implemented and integrated the EUF interpolation system together with propositional interpolation into the OpenSMT2 solver and HiFrog, an interpolation-based incremental model checker for C [6]. We report experiments in two different settings in the implementation: running the approach (i) integrated in HiFrog; and (ii) over unsatisfiable EUF benchmarks from SMT-LIB (i.e., the QF_UF benchmarks). The benchmarks and the software are available at http://verify.inf.usi.ch/euf-interpolation. Before describing the experiments we give a concise explanation on how EUF and propositional interpolants are integrated.

**A. Integration of Propositional and EUF Interpolation.**

An SMT solver takes as input a propositional formula where some atoms are interpreted as equalities or inequalities over a theory, that in our experiments is the theory of equalities over uninterpreted functions. If a satisfying truth assignment for the propositional structure is found, a theory solver is queried to determine the consistency of its equalities. In case of inconsistency the theory solver adds a reasoning-entailing clause to the propositional structure. The process ends when either a theory-consistent truth assignment is found or the propositional structure becomes unsatisfiable. The SMT framework provides a natural integration for the theory and propositional interpolants. The clauses provided by the theory solver are annotated with their theory interpolant and are used as partial interpolants in the propositional interpolation system (see, e.g., [15]). Similar to EUF, the propositional interpolation algorithms control the strength of the resulting interpolant by choosing the partition for the shared variables through labeling [15]. The labeling has to be followed then by the theory interpolation algorithm to preserve interpolant soundness. In the following experiments we use instances
of the propositional labeled interpolation system [28], [15] supported by OpenSMT2, and in particular the McMillan’s algorithms \(M_s\) and \(M_w\) [7], the Pudlák’s algorithm \(P\) [29], and the proof-sensitive algorithms \(PS, PS_s\), and \(PS_w\) [15] that use the proof structure to optimize the labeling. Fig. 4 shows the algorithms ordered with respect to the logical strength of the interpolants they compute.

### B. Interpolation-Based Incremental Verification

We integrated the EUF-interpolation system with the incremental model checker HiFrog as part of OpenSMT2, and used it to verify a set of C benchmarks from SV-COMP (https://sv-comp.sosy-lab.org/) and other sources. In total we checked 973 verification conditions over these problems in the experiments.

We use both purely propositional logic and QF_UF to model the programs. The incremental C model checker HiFrog attempts to prove or refute the validity of a sequence of verification conditions using an SMT solver and an encoding in EUF or in bit-precise propositional logic. Figure 3 shows HiFrog’s verification flow. The problem instance is first pre-processed and then encoded into an instance of a decision problem in SMT. An SMT solver computes whether the assertion holds by determining the satisfiability of the instance. If the instance is unsatisfiable, the assertion holds, and interpolation is used to extract function summaries from the proof. These summaries are then stored and used in lieu of the precise encoding of a function to incrementally verify the consequent assertions. If the instance is satisfiable, the witnessing truth assignment corresponds to an execution violating the assertion. However, due to the over-approximative nature of both EUF and the function summaries, the execution might be spurious. In this case the model checker uses the precise encoding instead of the summaries to decide the correct answer.

Table I gives an overview of our results. In parentheses after the names we mark the total number of assertions in the instance. The table shows the verification time for HiFrog with propositional logic in the column \(Bool\); and with EUF in the columns marked \(EUF Time\). Unlike the bit-precise propositional model, the EUF model provides an over-approximation of the program behavior. If HiFrog reports that a safety property is true under EUF it is also true for the propositional model. However, if a property is reported false, it may indicate either a real or a spurious counterexample introduced by the EUF abstraction. In case of false properties the model checker can for instance consult the propositional encoding to get the correct result. The three columns under the label \(EUF Results\) list, from left to right, the number of correctly identified assertions using EUF encoding, the number of reachable assertions, and how many of the reachable assertions were spurious. The table reports run times for three variations of the model checker. Column \(EUF\) reports the time used only by the EUF check. Column \(Sp\) reports the time when HiFrog is allowed to query the spuriousness of the counterexample from an oracle and only needs to consult the propositional encoding if the answer is yes. Column \(Full\) reports the time when HiFrog needs to resort to the propositional encoding always in case of a failure to verify. Notably the use of EUF as an abstraction technique usually speeds up the solving even in the case of the full overhead.

Finally we report the effect of interpolation algorithm on the set of C benchmarks.

</table>
combinations, demonstrating the advantage of the flexibility our framework provides for the EUF-interpolation. The number of summary refinement shows the total number of function summaries that were used in whole verification process, did not work, and were replaced by precise encoding of functions, hence the smaller number is, the more efficient is the solving process. The best-performing algorithm in this benchmark set is $M_w + Itp_s$ with both lowest total run time and the lowest total number of refinements. We note that the run time and the number of refinements do not always correlate, and that in particular the combination $M_s + Itp_s$ works very well with respect to refinements while losing nevertheless clearly in total run time.

Our experiments with a model checker solving real life problems shows two main results. The first is that using EUF to represent software instead of only Boolean formulas is beneficial, and leads to an impressive speed up in verification time. The second result, is that it is important to fine tune the interpolation algorithms used for Boolean and EUF interpolation in order to ultimately optimize convergence in the model checker.

C. Interpolation over SMT-LIB Benchmarks

In addition to integrating the EUF interpolation into the model checker, we also report a more controlled set of experiments on generating interpolants of different strength and size. We computed interpolants from over 2000 benchmarks from the QF_UF category of SMT-LIB, and report here the results of 106 benchmarks that resulted in non-trivial interpolation instances having complex EUF proofs with large congruence graphs. In total this set contains over two and a half million individual EUF interpolants. Following [17], [30], we randomly split the assertions in each benchmark to partitions $A$ and $B$.

a) Logical strength: The theory interpolation algorithms use three labeling functions $L_s$, $L_w$ (see Sec. III), and $L_r$, a labeling function that labels all components randomly as either $s$ or $w$. The algorithms are called, respectively, $Itp_s$, $Itp_w$, and $Itp_r$. We use the proof-sensitive interpolation algorithm [15] in the propositional structure. This results in three final interpolants $I_s$, $I_w$, and $I_r$, for each benchmark.

We computed the strength relationship for each theory partial interpolant as well as the final SMT interpolants. Even though the EUF interpolants are often simple, in 71% of them it was possible to generate at least two interpolants of different strength, and 5.7% resulted in all three having different strength.

After solving and interpolating, we ran extra experiments to check the strength relations of the final interpolants $I_s$, $I_w$, and $I_r$. Since the final interpolants are much more complex, of the 106 benchmarks, 55 ran out of memory while computing the strength relations. For the remaining 51, all the three final interpolants were pairwise inequivalent, confirming that the framework is able to generate interpolants of different strength.

b) Interpolant size: Since the propositional and EUF interpolation algorithms are to a large degree independent, it is natural to ask what combination of the algorithms is most efficient. This experiment studies the question using the interpolant size as a measure of efficiency. The six propositional and three EUF interpolation algorithms result in 18 combinations. We measure the sizes of the final interpolants both in (i) the number of Boolean connectives (Fig. 5); and (ii) the number of EUF equalities (Fig. 6). Excluding the instances where we encountered memory outs we report the results on 82 of the original 106 benchmarks. For each benchmark, we computed the smallest number of Boolean connectives or equalities in the interpolant among all the configurations (best) and the ratio combination/best for each possible combination, which shows us how much worse each combination did compared to the best combination for that benchmark. Notice that the ratio of the best combination for a benchmark is one and therefore no ratio can be less than one. The bars present the average and the crosses the median of those ratios among all the benchmarks for each combination.

In Fig. 5 the combination $M_w + Itp_w$ gives the smallest number of Boolean connectives, and $M_s + Itp_s$ appears in the second place. The median of $M_w + Itp_w$ is 1, which means that it was responsible for the smallest number of connectives in at least half of the benchmarks, and its average of 1.2 shows that even when this was not the case, the combination was still close to the optimum. On the losing side, we make two observations. The EUF interpolation algorithm $Itp_r$ leads to a larger number of Boolean connectives, and the propositional interpolation algorithm $P$ leads to larger interpolants.
Interestingly the combinations $PS + Itp_s$ and $PS_s + Itp_s$ have low medians and average, which are good, but not the best. This seemingly contradicts our earlier observation in [15] that $PS$ and $PS_s$ consistently lead to small number of connectives in the interpolant. Based on the experiments the likely reason is the soundness restriction in integration (see Sec. IV-A), since the results get gradually worse when the propositional and the EUF interpolation algorithms disagree more on the labeling, best being $PS_s + Itp_s$ and the worst $PS_w + Itp_w$.

The same trend is seen in Fig. 6 in the number of EUF equalities. A strong propositional interpolation algorithm ($M_s$, $PS_s$) combined with $Itp_s$ leads to smaller interpolants compared to their combination with $Itp_w$; and a weak propositional interpolation algorithm ($M_w$, $PS_w$) combined with $Itp_w$ leads to smaller interpolants compared to their combination with $Itp_s$. Interestingly $PS$, a propositional interpolation algorithm that tends to balance the distribution of variables [15], leads to very similar results when combined with $Itp_s$ and $Itp_w$.

Our experiments with interpolation over complex SMT benchmarks show that the interpolants generated by the EUF system presented in this work indeed have strictly different logical strength. Moreover, in the combination of Boolean and EUF interpolants, it is important to match the strength of the used interpolation algorithms in order to reduce the size of the generated interpolants.

V. CONCLUSIONS

We present and analyse a new interpolation framework for the theory of Equalities and Uninterpreted Functions, capable of generating interpolants of different strength and small size in a controlled way. The technique bases on the use of dual partial interpolants parameterized by a labeling function. We confirm the analysis with experiments and show the feasibility of generating multiple interpolants of different strengths. In addition, we report on the size of the created interpolants, comparing different combinations of propositional and EUF interpolation algorithms. Our major contribution work is the integration of a complete interpolation-based model checker to the system, and showing the significant impact the interpolant strength has on both run time and convergence.

In the future we intend to generalize the approach to be applicable to other theories, and study the effects of different labeling functions on fix-point computation in other model-checking applications.

REFERENCES

Theorem 2. Given two sets of equations and disequalities $A$ and $B$ such that $A \cup B$ is unsatisfiable, $G^C$, a colored congruence graph containing a path $\pi := \overrightarrow{xy}$ such that $(x \neq y) \in A \cup B$ and a labeling function $L$, Eq. (5) computes a valid interpolant for $A$ using $L$ over $G^C$.

Proof: In order to analyze Eq. (5) we have to analyze Eq. (8), Eq. (9), Eq. (6) and Eq. (7).

(i) $I_A(\pi)$

Eq. (8) is the same presented in [17], and computes interpolants for $A$ when the disequality $(x \neq y)$ is in $A$.

(ii) $I_B(\pi)$

Eq. (9) is the dual of Eq. (8), and clearly computes interpolants for $B$ when the disequality is in $B$. We can transform it into an interpolant for $A$ by negating it, as it is done in Eq. (5).

(iii) $I_A(\pi)$

Eq. (6) behaves similarly to the interpolation procedure presented in [17], with the addition of dual interpolants and labeling functions. First $I_A$ computes the individual contribution of the $A$-factors that prove $\pi$ in $G^C$ ($A(\pi)$) to the interpolant, and then conjoints it with the interpolants of their $B$-premise sets ($B(\pi)$).

(iv) $I_B(\pi)$

Eq. (7) is the dual of Eq. (6) and computes an interpolant for $B$, which can be transformed into an interpolant for $A$ by negating it.

Definition 2: Let $G$ be a congruence graph, and $\sigma$ an arbitrary factor from $G$. We say that $\sigma$ is relevant to $\omega$ if either $J_A(\sigma)$ or $J_B(\sigma)$ is called during the computation of $I_A(\omega)$ or $I_B(\omega)$.

Lemma 2. Let $G^C$ be a congruence graph with coloring $C$, and $\omega$ a factor from $G$. Then $I_A(\omega) \land I_B(\omega) \rightarrow [\omega]$.

Proof: Let $R^\omega$ be the set of factors relevant (Def. 2) to $\omega$ in a congruence graph, $R^\omega_A$ the subset of $R^\omega$ containing only $A$-factors and $R^\omega_B$ the subset of $R^\omega$ containing only $B$-factors.

From Eq. (6) we can clearly see that

$$R^\omega_A := A(\omega) \cup A(BA(\omega)) \cup \ldots \cup A((BA)^k(\omega)) \cup \ldots,$$

and from Eq. (7) that

$$R^\omega_B := B(\omega) \cup B(AB(\omega)) \cup \ldots \cup B((AB)^k(\omega)) \cup \ldots.$$  \hfill (10)

Because congruence graphs are acyclic and finite, for any $\omega$ there exists an integer $n$ such that $A((BA)^n(\omega)) = {}$ and $B((AB)^n(\omega)) = {}$, which allows us to rewrite the previous equations as

$$R^\omega_A := A(\omega) \cup A(BA(\omega)) \cup \ldots \cup A((BA)^k(\omega)),$$ \hfill (12)

$$R^\omega_B := B(\omega) \cup B(AB(\omega)) \cup \ldots \cup B((AB)^k(\omega)).$$ \hfill (13)

If $\omega$ is an $A$-factor, we have that $A(\omega) = \{\omega\}$ and therefore we can write $B(\omega) \equiv BA(\omega)$. Using that we can infer that $A((BA)^n(\omega)) = {}$ (by the definition of $n$), and we can change Eq. (13) to

$$R^\omega_B := BA(\omega) \cup (BA)^2(\omega) \cup \ldots \cup (BA)^n(\omega).$$ \hfill (14)

We follow the proof assuming that $\omega$ is an $A$-factor, using Eq. (12) and Eq. (14) to represent $R^\omega_A$ and $R^\omega_B$ respectively, and then argue that the proof is symmetrical for the case where $\omega$ is a $B$-factor.

From Eq. (12) and Eq. (14), we can then see that

$$R^\omega := A(\omega) \cup BA(\omega) \cup A(BA(\omega)) \cup \ldots \cup A((BA)^n(\omega)) \cup (BA)^{n+1}(\omega)$$ \hfill (15)

and therefore

$$I_A(\omega) \land I_B(\omega) = (\bigwedge_{\sigma \in R^\omega_A} J_A(\sigma)) \land (\bigwedge_{\sigma \in R^\omega_B} J_B(\sigma)).$$ \hfill (16)

When $J_A$ and $J_B$ are computed over a set that has an empty premise set, the result is not a conjunction of implications, but a conjunction of equalities. In this case, $J_B((BA)^{n+1}(\omega)) = (BA)^{n+1}(\omega)$ because $A((BA)^n(\omega)) = \emptyset$. Thus, after applying the functions $J_A$ and $J_B$ we have that

$$I_A(\omega) \land I_B(\omega) = (\bigwedge_{i=0}^{n} (A(BA)^i(\omega)) \rightarrow [\omega])$$ \hfill (17)

We know that formulas of the form $((a_1 \rightarrow b_1) \land \ldots \land (a_n \rightarrow b_n)) \rightarrow ((\bigwedge_{i=1..n} a_i) \rightarrow (\bigwedge_{i=1..n} b_i))$ are tautologies. Using that and Eq. (17), we can then show that

$$I_A(\omega) \land I_B(\omega) \rightarrow (\bigwedge_{i=0}^{n} (A((BA)^i(\omega)) \rightarrow [\omega]))$$ \hfill (18)

$$I_A(\omega) \land I_B(\omega) \rightarrow (\bigwedge_{i=0}^{n} (A((BA)^i(\omega)) \rightarrow [\omega]))$$ \hfill (19)

Therefore, we have that

$$\forall \tau \in R^\omega, (I_A(\omega) \land I_B(\omega)) \rightarrow [\tau].$$ \hfill (20)

For the case where $\omega$ is a $B$-factor, we have that $B(\omega) = \{\omega\}$, which implies that $AB(\omega) \equiv A(\omega)$. Using that, we can infer that $B((BA)^{n+1}(\omega)) = \emptyset$ and we can also change Eq. (12) to

$$R^\omega_A := AB(\omega) \cup (AB)^2(\omega) \cup \ldots \cup (AB)^n(\omega).$$ \hfill (21)

Using Eq. (21) and Eq. (13) to represent $R^\omega_A$ and $R^\omega_B$ respectively, the same reasoning is followed and we can show that Eq. (20) holds also if $\omega$ is a $B$-factor.

If $\omega$ is an $A$-factor, then $A(\omega) = \{\omega\}$ and $J_A$ is called for $\omega$ in the first iteration of Eq. (6). On the other hand, if $\omega$ is a $B$-factor, then $B(\omega) = \{\omega\}$ and $J_B$ is called for $\omega$ in the first iteration of Eq. (7). This shows that $\omega$ is a relevant factor and by Eq. (20) we conclude the proof.
Lemma 3. Let $\pi$ be an arbitrary path in the congruence graph, and $\phi(\pi)$ the set of all factors in $\pi$. Then $I_A(\pi) = \bigwedge_{\sigma \in \phi(\pi)} I_A(\sigma)$ and $I_B(\pi) = \bigwedge_{\sigma \in \phi(\pi)} I_B(\sigma)$.

Proof: By the definition of $A$ in Eq. (2), we know that $A(\pi) = \bigcup_{\sigma \in \phi(\pi)} A(\sigma)$. By the definition of $I_A$, we can see that $J_A$ is computed individually for each element of $A(\pi)$ in $I_A(\pi)$, and $I_A$ is called recursively for the B-premise sets of each individual element of $A(\pi)$. Therefore, $\bigwedge_{\sigma \in \phi(\pi)} I_A(\sigma) = \bigwedge_{\sigma \in \phi(\pi)} I_A(\sigma)$, which has the same effect of $I_A(\pi)$. The result is analogous for $I_B(\pi)$.

Lemma 4. Lemma 2 holds when $\omega$ is a path containing multiple factors.

Proof: Let $\omega$ be a path built by multiple factors and $\phi(\omega)$ the set containing these factors. By Lemma 3 we know that $I_A(\omega) = \bigwedge_{\sigma \in \phi(\omega)} I_A(\sigma)$ and $I_B(\omega) = \bigwedge_{\sigma \in \phi(\omega)} I_B(\sigma)$; by Lemma 2 we know that $\forall \sigma \in \phi(\omega), (I_A(\sigma) \land I_B(\sigma)) \rightarrow [\sigma]$. Because the elements of $\phi(\omega)$ are factors linking nodes to prove $\omega$, we know that $\bigwedge_{\sigma \in \phi(\omega)} [\sigma] \rightarrow [\omega]$. Therefore we have that $I_A(\omega) \land I_B(\omega) \rightarrow [\omega]$.

Theorem 3. For fixed $A, B, G^C$, and $\overline{\pi}$ for the corresponding interpolants defined in Eq. (5) it holds that $Itp(A, B, G^C, \overline{\pi}, L_s) \rightarrow Itp(A, B, G^C, \overline{\pi}, L_w)$.

Proof: We only consider the case where $(x \neq y) \in B$ and note that the case where $(x \neq y) \in A$ is completely symmetrical. Let $\pi := \overline{\pi}y$ and $\psi := I_A(\pi) \land I_B(\pi)$. By Eq. (9) we have that

$$
\psi = I_B(\theta_\pi) \land \\
\left( \bigwedge_{\sigma \in A(\pi) \cup A(\pi_2)} I_B(\sigma) \right) \land \\
\left( [A(\pi_1) \cup A(\pi_2)] \rightarrow [\neg \theta_\pi] \right) \land I_A(\pi),
$$

where $\pi$ is decomposed as $\pi_1 \theta_\pi \pi_2$, and $\theta_\pi$ is the largest subpath of $\pi$ with $A$-colorable endpoints. In order to show that $I_A(\pi) \rightarrow I_B(\pi)$, we prove that $\psi \rightarrow \bot$, which leads to the theorem. In $I_B(\pi)$, $\pi$ is split into $\pi_1 \theta_\pi \pi_2$, from the definition of $\theta_\pi$, we know that $\pi_1$ and $\pi_2$ are $B$-factors. Therefore, using Lemma 3, we know that $\forall \sigma \in A(\pi_1) \cup A(\pi_2), I_A(\sigma) \land I_B(\pi_2)$. Because $\pi_1$ and $\pi_2$ are subpaths of $\pi$, we know that $A(\pi_1) \land A(\pi_2) \subseteq A(\pi)$. Using Lemma 3, we have that $I_A(\pi_1) \land I_A(\pi_2) = \bigwedge_{\sigma \in A(\pi_1)} I_A(\sigma) \land \bigwedge_{\sigma \in A(\pi_2)} I_A(\sigma)$. We can now see that both $\bigwedge_{\sigma \in A(\pi_1) \cup A(\pi_2)} I_B(\sigma)$ and $\bigwedge_{\sigma \in A(\pi_1) \cup A(\pi_2)} I_A(\sigma)$ are contained in $\psi$. From Lemma 2 we know that (i) $\psi \rightarrow [A(\pi_1) \land A(\pi_2)]$, $I_A(\theta_\pi)$ and $I_B(\theta_\pi)$ are also contained in $\psi$, therefore from Lemma 2 we have that (ii) $\psi \rightarrow [\neg \theta_\pi]$. From (i) and (ii) we see that $\psi \rightarrow ([\theta_\pi] \land [\neg \theta_\pi])$.

From Eq (6) we can see that when a factor $\sigma$ has label $a$ a weakening step is applied, using $-I_B(\pi)$ instead of $I_A(\pi)$. Let $Itp$ be the interpolant generated without weakening, and $Itp'$ the interpolant generated having applied the weakening step. We know that $I_A(\pi) \subseteq Itp$ and $-I_B(\pi) \subseteq Itp'$. From Theorem 3 we know that $I_A(\pi) \rightarrow I_B(\pi)$. Therefore we have that $Itp \rightarrow Itp'$.

Following the same reasoning, from Eq. (7) we can see that when a factor $\sigma$ has label $b$ a strengthening step is applied, using $-I_B(\pi)$ instead of $I_B(\pi)$. Let $Itp$ be the interpolant generated without strengthening, and $Itp'$ the interpolant generated having applied this strengthening step. We know that $-I_B(\pi) \subseteq Itp$ and $-I_B(\pi) \subseteq Itp'$. From Theorem 3 we have that $I_A(\pi) \rightarrow I_B(\pi)$. Therefore we have that $Itp \rightarrow Itp'$.

Theorem 5. Let $Itp_L = (A, B, G^C[I_A(\sigma)])$. If $\pi \in B, L = L_s$ leads to the interpolant that contains the smallest number of equalities, and if $\pi \in A, L = L_w$ leads to the interpolant that contains the smallest number of equalities.

Proof: Consider the labeling function $L_s$ and the computation of $I_A(\pi)$. The usage of this labeling function makes the formula be entirely computed by $I_A$, never using $I_B$. Now let $I_A(\delta)$ be some arbitrary subcomputation of $I_A(\pi)$. First, $\bigwedge_{\sigma \in A(\delta)} J_A(\sigma)$ is computed. From Eq. 3 we know that this formula contains the equality $[\sigma_A]$ for every $\sigma_A \in A(\delta)$ and the equality $[\sigma_B]$ for every $\sigma_B \in B(\delta)$. Suppose then that a factor $\gamma$ from $B(\delta)$ has label $w$, which results in the computation of $-I_B(\gamma)$. We know that $\gamma$ is a $B$-factor because it came from $B(\delta)$, therefore (i) $\theta_\gamma = \gamma$; and (ii) $B(\gamma) = \{\gamma\}$. From (i) we have that $I_B(\gamma)$ computes $I_B(\gamma)$, and from (ii) we have that $B(\gamma) = \{\gamma\}$ and $J_B(\gamma)$ is then computed. This reintroduces $[\gamma]$ in the interpolant (as the implicated part of $J_B(\gamma)$), since $I_A(\delta)$ already introduced it in the implicant of some implication in $\bigwedge_{\sigma \in A(\delta)} J_A(\sigma)$. Notice if $\gamma$ had label $s$ this equality would not be reintroduced. The reasoning is symmetrical for the case where $L_w$ is used for the computation of $I_B$. Therefore we have that $I_A(\pi)$ and $I_B(\pi)$ contain exactly the same equalities, with the difference being the side of the implication (implicant or implicated) that an equality appears in (because of Eq. 3 and Eq. 4). We can also see that any other labeling function $L$ will introduce at least one equality in the interpolant more than once (when it changes from $I_A$ to $-I_B'$ or from $I_B$ to $-I_A'$).

If $\pi \in B$, an interpolant can be computed by either $I_A(\pi)$ or $I_A(\pi')$. The interpolant $I_A(\pi)$ has less equalities because it does not introduce the conflict in the interpolant, as $-I_B(\pi)$ does with the term $([A(\pi_1) \cup A(\pi_2)] \rightarrow [\neg \theta_\pi])$. Therefore, $L_s$ leads to the interpolant with the least number of equalities.

If $\pi \in A$, an interpolant can be computed by either $-I_B(\pi)$ or $-I_B(\pi')$. Symmetrically, the interpolant $-I_B(\pi)$ has less equalities because it does not introduce the conflict in the interpolant, as $I_A(\pi)$ does with the term $([B(\pi_1) \cup B(\pi_2)] \rightarrow [\neg \theta_B])$. Therefore, $L_w$ leads to the interpolant with the least number of equalities.
