Exercises for Algorithms and Data Structures

Antonio Carzaniga
Faculty of Informatics
USI
(Università della Svizzera italiana)

Edition 2.5
February 2018
(with some solutions)
Exercise 1. Answer the following questions on the big-oh notation.

Question 1: Explain what \( g(n) = O(f(n)) \) means. (5')

Question 2: Explain why it is meaningless to state that "the running time of algorithm A is at least \( O(n^2) \)." (5')

Question 3: Given two functions \( f = \Omega(\log n) \) and \( g = O(n) \), consider the following statements. For each statement, write whether it is true or false. For each false statement, write two functions \( f \) and \( g \) that show a counter-example. (5')

- \( g(n) = O(f(n)) \)
- \( f(n) = O(g(n)) \)
- \( f(n) = \Omega(\log (g(n))) \)
- \( f(n) = \Theta(\log (g(n))) \)
- \( f(n) + g(n) = \Omega(\log n) \)

Question 4: For each one of the following statements, write two functions \( f \) and \( g \) that satisfy the given condition. (5')

- \( f(n) = O(g^2(n)) \)
- \( f(n) = \omega(g(n)) \)
- \( f(n) = \omega(\log (g(n))) \)
- \( f(n) = \Omega(f(n)g(n)) \)
- \( f(n) = \Theta(g(n)) + \Omega(g^2(n)) \)

Exercise 2. Write an algorithm called FIND-LARGEST that finds the largest number in an array using a divide-and-conquer strategy. Also, write the time complexity of your algorithm in terms of big-oh notation. Briefly justify your complexity analysis. (20')

Exercise 3. Illustrate the execution of the merge-sort algorithm on the array

\[ A = \langle 3, 13, 89, 34, 21, 44, 99, 56, 9 \rangle \]

For each fundamental iteration or recursion of the algorithm, write the content of the array. Assume the algorithm performs an in-place sort. (20')

Exercise 4. Consider the array \( A = \langle 29, 18, 10, 15, 20, 9, 5, 13, 2, 4, 15 \rangle \).

Question 1: Does \( A \) satisfy the max-heap property? If not, fix it by swapping two elements. (5')

Question 2: Using array \( A \) (possibly corrected), illustrate the execution of the heap-extract-max algorithm, which extracts the max element and then rearranges the array to satisfy the max-heap property. For each iteration or recursion of the algorithm, write the content of the array \( A \). (15')

Exercise 5. Consider the following binary search tree (BST).

![Binary Search Tree](image)
Question 1: List all the possible insertion orders (i.e., permutations) of the keys that could have produced this BST.

Question 2: Draw the same BST after the insertion of keys: 6, 45, 32, 98, 55, and 69, in this order.

Question 3: Draw the BST resulting from the deletion of keys 9 and 45 from the BST resulting from question 2.

Question 4: Write at least three insertion orders (permutations) of the keys remaining in the BST after question 3 that would produce a balanced tree (i.e., a minimum-height tree).

Exercise 6. Implement a function that returns the successor of a node in a binary search tree (the BST stores integer keys). A successor of a node \( n \) is defined as the smallest key \( x \) in the BST such that \( x \) is bigger than the value of \( n \), or \( \text{null} \) if that does not exist. You may assume that the BST does not contain duplicate keys. The signature of the function you have to implement and the interface of the \( \text{TreeNode} \) class, which implements the BST, are given below. Note that \( \text{getLeft()}, \text{getRight()}, \) and \( \text{getParent()} \) return \( \text{null} \) if the node does not have a left, a right child, or is the root, respectively.

```
interface TreeNode {
    int getValue();
    TreeNode getLeft();
    TreeNode getRight();
    TreeNode getParent();
}
```

Exercise 7. Consider a hash table that stores integer keys. The keys are 32-bit unsigned values, and are always a power of 2. Give the minimum table size \( t \) and the hash function \( h(x) \) that takes a key \( x \) and produces a number between 1 and \( t \), such that no collision occurs.

Exercise 8. Explain why the time complexity of searching for elements in a hash table, where conflicts are resolved by chaining, decreases as its load factor \( \alpha \) decreases. Recall that \( \alpha \) is defined as the ratio between the total number of elements stored in the hash table and the number of slots in the table.

Exercise 9. For each statement below, write whether it is true or false. For each false statement, write a counter-example.

- \( f(n) = \Theta(n) \land g(n) = \Omega(n) \Rightarrow f(n)g(n) = \Omega(n^2) \)
- \( f(n) = \Theta(1) \Rightarrow n^{f(n)} = O(n) \)
- \( f(n) = \Omega(n) \land g(n) = O(n^2) \Rightarrow g(n)/f(n) = O(n) \)
- \( f(n) = O(n^2) \land g(n) = O(n) \Rightarrow f(g(n)) = O(n^3) \)
- \( f(n) = O(\log n) \Rightarrow 2^{f(n)} = O(n) \)
- \( f = \Omega(\log n) \Rightarrow 2^{f(n)} = \Omega(n) \)

Exercise 10. Write tight asymptotic bounds for each one of the following definitions of \( f(n) \).

- \( g(n) = \Omega(n) \land f(n) = g(n)^2 + n^3 \Rightarrow f(n) = \)
- \( g(n) = O(n^2) \land f(n) = n \log(g(n)) \Rightarrow f(n) = \)
- \( g(n) = \Omega(\sqrt{n}) \land f(n) = g(n + 2^{16}) \Rightarrow f(n) = \)
- \( g(n) = \Theta(n) \land f(n) = 1 + 1/\sqrt{g(n)} \Rightarrow f(n) = \)
- \( g(n) = O(n) \land f(n) = 1 + 1/\sqrt{g(n)} \Rightarrow f(n) = \)
\[ g(n) = O(n) \land f(n) = g(g(n)) \Rightarrow f(n) = \]

►Exercise 11. Write the ternary-search trie (TST) that represents a dictionary of the strings: “gnu” “emacs” “gpg” “else” “gnome” “go” “eps2eps” “expr” “exec” “google” “elif” “email” “exit” “epstopdf”

Exercise 12. Answer the following questions.

Question 1: A hash table with chaining is implemented through a table of \( K \) slots. What is the expected number of steps for a search operation over a set of \( N = K/2 \) keys? Briefly justify your answers.

Question 2: What are the worst-case, average-case, and best-case complexities of insertion-sort, bubble-sort, merge-sort, and quicksort?

►Exercise 13. Write the pseudo code of the in-place insertion-sort algorithm, and illustrate its execution on the array

\[ A = \langle 7, 17, 89, 74, 21, 7, 43, 9, 26, 10 \rangle \]

Do that by writing the content of the array at each main (outer) iteration of the algorithm.

►Exercise 14. Consider a binary tree containing \( N \) integer keys whose values are all less than \( K \), and the following FIND-PRIME algorithm that operates on this tree.

\[
\begin{align*}
\text{FIND-PRIME}(T) & \quad \text{IS-PRIME}(n) \\
1 \quad x = \text{Tree-Min}(T) & \quad 1 \quad i = 2 \\
2 \quad \text{while } x \neq \text{NIL} & \quad 2 \quad \text{while } i \cdot i \leq n \\
3 \quad x = \text{Tree-Successor}(x) & \quad 3 \quad \text{if } i \text{ divides } n \\
4 \quad \text{if } \text{IS-PRIME}(x.\text{key}) & \quad 4 \quad \text{return } \text{FALSE} \\
5 \quad \text{return } x & \quad 5 \quad i = i + 1 \\
6 \quad \text{return } x & \quad 6 \quad \text{return } \text{TRUE}
\end{align*}
\]

Hint: these are the relevant binary-tree algorithms.

\[
\begin{align*}
\text{Tree-Successor}(x) & \quad \text{Tree-Minimum}(x) \\
1 \quad \text{if } x.\text{right} \neq \text{NIL} & \quad 1 \quad \text{while } x.\text{left} \neq \text{NIL} \\
2 \quad \text{return } \text{Tree-Minimum}(x.\text{right}) & \quad 2 \quad x = x.\text{left} \\
3 \quad y = x.\text{parent} & \quad 3 \quad \text{return } x \\
4 \quad \text{while } y \neq \text{NIL} \text{ and } x = y.\text{right} & \quad 4 \quad \text{return } y \\
5 \quad x = y & \quad 5 \quad y = y.\text{parent} \\
6 \quad y = y.\text{parent} & \quad 6 \quad \text{return } y \\
7 \quad \text{return } y
\end{align*}
\]

Write the time complexity of FIND-PRIME. Justify your answer.

►Exercise 15. Consider the following max-heap

\[ H = \langle 37, 12, 30, 10, 3, 9, 20, 3, 7, 1, 7, 5 \rangle \]

Write the exact output of the following EXTRACT-ALL algorithm run on \( H \)

\[
\begin{align*}
\text{EXTRACT-ALL}(H) & \quad \text{HEAP-EXTRACT-MAX}(H) \\
1 \quad \text{while } H.\text{heap-size} > 0 & \quad 1 \quad \text{if } H.\text{heap-size} > 0 \\
2 \quad \text{HEAP-EXTRACT-MAX}(H) & \quad 2 \quad k = H[1] \\
3 \quad \text{for } i = 1 \text{ to } H.\text{heap-size} & \quad 3 \quad H[1] = H[H.\text{heap-size}] \\
4 \quad \text{output } H[i] & \quad 4 \quad H.\text{heap-size} = H.\text{heap-size} - 1 \\
5 \quad \text{output "." END-OF-LINE} & \quad 5 \quad \text{MAX-HEAPIFY}(H) \\
6 \quad \text{return } k
\end{align*}
\]
Exercise 16. Develop an efficient in-place algorithm called PARTITION-EVEN-ODD(A) that partitions an array A in even and odd numbers. The algorithm must terminate with A containing all its even elements preceding all its odd elements. For example, for input A = (7, 17, 74, 21, 7, 9, 26, 10), the result might be A = (74, 10, 26, 17, 7, 21, 9, 7). PARTITION-EVEN-ODD must be an in-place algorithm, which means that it may use only a constant memory space in addition to A. In practice, this means that you may not use another temporary array.

Question 1: Write the pseudo-code for PARTITION-EVEN-ODD. (20')

Question 2: Characterize the complexity of PARTITION-EVEN-ODD. Briefly justify your answer. (10')

Question 3: Formalize the correctness of the partition problem as stated above, and prove that PARTITION-EVEN-ODD is correct using a loop-invariant. (20')

Question 4: If the complexity of your algorithm is not already linear in the size of the array, write a new algorithm PARTITION-EVEN-ODD-OPTIMAL with complexity O(N) (with N = |A|). (20')

Exercise 17. The binary string below is the title of a song encoded using Huffman codes.

0011000101111101100111011101100000100111010010101

Given the letter frequencies listed in the table below, build the Huffman codes and use them to decode the title. In cases where there are multiple “greedy” choices, the codes are assembled by combining the first letters (or groups of letters) from left to right, in the order given in the table. Also, the codes are assigned by labeling the left and right branches of the prefix/code tree with ‘0’ and ‘1’, respectively.

<table>

Exercise 18. Consider the text and pattern strings:

text: momify my mom please
pattern: mom

Use the Boyer-Moore string-matching algorithm to search for the pattern in the text. For each character comparison performed by the algorithm, write the current shift and highlight the character position considered in the pattern string. Assume that indexes start from 0. The following table shows the first comparison as an example. Fill the rest of the table. (10')

<table>
<thead>
<tr>
<th>n.</th>

</table>

Exercise 19. You wish to create a database of stars. For each star, the database will store several megabytes of data. Considering that your database will store billions of stars, choose the data structure that will provide the best performance. With this data structure you should be able to find, insert, and delete stars. Justify your choice. (10')

Exercise 20. You are given a set of persons P and their friendship relation R. That is, (a, b) ∈ R if and only if a is a friend of b. You must find a way to introduce person x to person y through a chain of friends. Model this problem with a graph and describe a strategy to solve the problem. (10')

Exercise 21. Answer the following questions

Question 1: Explain what \( f(n) = \Omega(g(n)) \) means. (5')

Question 2: Explain what kind of problems are in the P complexity class. (5')

Question 3: Explain what kind of problems are in the NP complexity class. (5')

Question 4: Explain what it means for problem A to be polynomially-reducible to problem B. (5')

Question 5: Write true, false, or unknown depending on whether the assertions below are true, false, or we do not know. (5')
• \( P \subseteq NP \)

• \( NP \subseteq P \)

• \( n! = O(n^{100}) \)

• \( \sqrt{n} = \Omega(\log n) \)

• \( 3n^2 + \frac{1}{n} + 4 = \Theta(n^2) \)

**Question 6:** Consider the exact change problem characterized as follows. 
*Input:* a multiset of values \( V = \{v_1, v_2, \ldots, v_n\} \) representing coins and bills in a cash register; a value \( X \); 
*Output:* 1 if there exists a subset of \( V \) whose total value is equal to \( X \), or 0 otherwise. Is the exact-change problem in \( NP \)? Justify your answer.

**Exercise 22.** A thief robbing a gourmet store finds \( n \) pieces of precious cheeses. For each piece \( i \), \( v_i \) designates its value and \( w_i \) designates its weight. Considering that \( W \) is the maximum weight the robber can carry, and considering that the robber may take any fraction of each piece, you must find the quantity of each piece the robber must take to maximize the value of the robbery. 

**Question 1:** Devise an algorithm that solves the problem using a greedy or dynamic programming strategy.

**Question 2:** Prove the problem exhibits an optimal substructure. Moreover, if you used a greedy strategy, show that the greedy choice property holds for your algorithm.  
(Hint: the greedy-choice property holds if and only if every greedy choice is contained in an optimal solution; the optimization problem exhibits an optimal substructure if and only if an optimal solution to the problem contains within it optimal solutions to subproblems.)

**Question 3:** Compute the time complexity of your solution.

```c
/* Outputs the quantity of each piece taken */
float[] knapSack(int[] v, int[] w, int W) {

**Exercise 23.** You are in front of a stack of pancakes of different diameter. Unfortunately, you cannot eat them unless they are sorted according to their size, with the biggest one at the bottom. To sort them, you are given a spatula that you can use to split the stack in two parts and then flip the top part of the stack. Write the pseudo-code of a function sortPancakes that sorts the stack. The \( i \)-th element of array pancakes contains the diameter of the \( i \)-th pancake, counting from the bottom. The sortPancakes algorithm can modify the stack only through the spatulaFlip function whose interface is specified below. 
(Hint: Notice that you can move a pancake at position \( x \) to position \( y \), without modifying the positions of the order of the other pancakes, using a sequence of spatula flips.)

```c
/* Flips over the stack of pancakes from position pos and returns the result */
int[] spatulaFlip(int pos, int[] pancakes);

int[] sortPancakes(int[] pancakes) {

**Exercise 24.** The following matrix represents a directed graph over vertices \( a, b, c, \ldots, \ell \). Rows and columns represent the source and destination of edges, respectively.
Sort the vertices in a reverse topological order using the depth-first search algorithm. (Hint: if you order the vertices from left to right in reverse topological order, then all edges go from right to left.) Justify your answer by showing the relevant data maintained by the depth-first search algorithm, and by explaining how that can be used to produce a reverse topological order.

Exercise 25. Answer the following questions on the complexity classes P and NP. Justify your answers.

Question 1: $P \subseteq NP$?

Question 2: A problem $Q$ is in $P$ and there is a polynomial-time reduction from $Q$ to $Q'$. What can we say about $Q'$? Is $Q' \in P$? Is $Q' \in NP$?

Question 3: Let $Q$ be a problem defined as follows. Input: a set of numbers $A = \{a_1, a_2, \ldots, a_N\}$ and a number $x$; Output: 1 if and only if there are two values $a_i, a_k \in A$ such that $a_i + a_k = x$. Is $Q$ in NP? Is $Q$ in P?

Exercise 26. Consider the subset-sum problem: given a set of numbers $A = \{a_1, a_2, \ldots, a_n\}$ and a number $x$, output true if there is a subset of numbers in $A$ that add up to $x$, otherwise output false. Formally, $\exists S \subseteq A$ such that $\sum_{y \in S} y = x$. Write a dynamic-programming algorithm to solve the subset-sum problem and informally analyze its complexity.

Exercise 27. Explain the idea of dynamic programming using the shortest-path problem as an example. (The shortest path problem amounts to finding the shortest path in a given graph $G = (V, E)$ between two given vertices $a$ and $b$.)

Exercise 28. Consider an initially empty B-Tree with minimum degree $t = 3$. Draw the B-Tree after the insertion of the keys 27, 33, 39, 1, 3, 10, 7, 200, 23, 21, 20, and then after the additional insertion of the keys 15, 18, 19, 13, 34, 200, 100, 50, 51.

Exercise 29. There are three containers whose sizes are 10 pints, 7 pints, and 4 pints, respectively. The 7-pint and 4-pint containers start out full of water, but the 10-pint container is initially empty. Only one type of operation is allowed: pouring the contents of one container into another, stopping only when the source container is empty, or the destination container is full. Is there a sequence of pourings that leaves exactly two pints in either the 7-pint or the 4-pint container?

Question 1: Model this as a graph problem: give a precise definition of the graph involved (type of the graph, labels on vertices, meaning of an edge). Provide the set of all reachable vertices, identify the initial vertex and the goal vertices. (Hint: all vertices that satisfy the condition imposed by the problem are reachable, so you don’t have to draw a graph.)

Question 2: State the specific question about this graph that needs to be answered?

Question 3: What algorithm should be applied to solve the problem? Justify your answer.

Exercise 30. Write an algorithm called MOVEToROOT($x, k$) that, given a binary tree rooted at node $x$ and a key $k$, moves the node containing $k$ to the root position and returns that node if $k$ is in the tree. If $k$ is not in the tree, the algorithm must return $x$ (the original root) without modifying the
tree. Use the typical notation whereby \( x.key \) is the key stored at node \( x \), \( x.left \) and \( x.right \) are the left and right children of \( x \), respectively, and \( x.parent \) is \( x \)'s parent node.

**Exercise 31.** Given a sequence of numbers \( A = \langle a_1, a_2, \ldots, a_n \rangle \), an increasing subsequence is a sequence \( a_{i_1}, a_{i_2}, \ldots, a_{i_k} \) of elements of \( A \) such that \( 1 \leq i_1 < i_2 < \ldots < i_k \leq n \), and such that \( a_{i_1} < a_{i_2} < \ldots < a_{i_k} \). You must find the longest increasing subsequence. Solve the problem using dynamic programming.

- **Question 1:** Define the subproblem structure and the solution of each subproblem.
- **Question 2:** Write an iterative algorithm that solves the problem. Illustrate the execution of the algorithm on the sequence \( A = \langle 2, 4, 5, 6, 7, 9 \rangle \).
- **Question 3:** Write a recursive algorithm that solves the problem. Draw a tree of recursive calls for the algorithm execution on the sequence \( A = \langle 1, 2, 3, 4, 5 \rangle \).
- **Question 4:** Compare the time complexities of the iterative and recursive algorithms.

**Exercise 32.** One way to implement a disjoint-set data structure is to represent each set by a linked list. The first node in each linked list serves as the representative of its set. Each node contains a key, a pointer to the next node, and a pointer back to the representative node. Each list maintains the pointers head, to the representative, and tail, to the last node in the list.

- **Question 1:** Write the pseudo-code and analyze the time complexity for the following operations:
  - **MAKE-SET(\( x \)):** creates a new set whose only member is \( x \).
  - **UNION(\( x, y \)):** returns the representative of the union of the sets that contain \( x \) and \( y \).
  - **FIND-SET(\( x \)):** returns a pointer to the representative of the set containing \( x \).

Note that \( x \) and \( y \) are nodes.

- **Question 2:** Illustrate the linked list representation of the following sets:
  - \( \{c, a, d, b\} \)
  - \( \{e, g, f\} \)
  - \( \text{UNION}(d,g) \)

**Exercise 33.** Explain what it means for a hash function to be perfect for a given set of keys. Consider the hash function \( h(x) = x \mod m \) that maps an integer \( x \) to a table entry in \( \{0, 1, \ldots, m-1\} \). Find an \( m \leq 12 \) such that \( h \) is a perfect hash function on the set of keys \( \{0, 6, 9, 12, 22, 31\} \).

**Exercise 34.** Draw the binary search tree obtained when the keys \( 1, 2, 3, 4, 5, 6, 7 \) are inserted in the given order into an initially empty tree. What is the problem of the tree you get? Why is it a problem? How could you modify the insertion algorithm to solve this problem. Justify your answer.

**Exercise 35.** Consider the following array:

\[ A = \{4, 33, 6, 90, 33, 32, 31, 91, 90, 89, 50, 33\} \]

- **Question 1:** Is \( A \) a min-heap? Justify your answer by briefly explaining the min-heap property.
- **Question 2:** If \( A \) is a min-heap, then extract the minimum value and then rearrange the array with the min-heapify procedure. In doing that, show the array at every iteration of min-heapify. If \( A \) is not a min-heap, then rearrange it to satisfy the min-heap property.

**Exercise 36.** Write the pseudo-code of the insertion-sort algorithm. Illustrate the execution of the algorithm on the array \( A = \{3, 13, 89, 34, 21, 44, 99, 56, 9\} \), writing the intermediate values of \( A \) at each iteration of the algorithm.

**Exercise 37.** Encode the following sentence with a Huffman code

*Common sense is the collection of prejudices acquired by age eighteen*

Write the complete construction of the code.
Exercise 38. Consider the text and query strings:

**text:** It ain’t over till it’s over.

**query:** over

Use the Boyer-Moore string-matching algorithm to search for the query in the text. For each character comparison performed by the algorithm, write the current shift and highlight the character position considered in the query string. Assume that indexes start from 0. The following table shows the first comparison as an example. Fill the rest of the table.

| n. | shift | l | t | a | i | n | ’t | o | v | e | r | t | i | l | l | i | t | ’s | o | v | e | r |
| 1  | 0      | o | v | e | r | t | i | l | l | i | t | ’s | o | v | e | r | t | i | l | l | i | t | ’s | o | v | e | r |
| 2  | 0      | o | v | e | r | t | i | l | l | i | t | ’s | o | v | e | r | t | i | l | l | i | t | ’s | o | v | e | r |
| ...| ...    |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Exercise 39. Briefly answer the following questions

**Question 1:** What does $f(n) = \Theta(g(n))$ mean? (5’)

**Question 2:** What kind of problems are in the $P$ class? Give an example of a problem in $P$. (5’)

**Question 3:** What kind of problems are in the $NP$ class? Give an example of a problem in $NP$. (5’)

**Question 4:** What does it mean for a problem $A$ to be reducible to a problem $B$? (5’)

Exercise 40. For each of the following assertions, write “true,” “false,” or “?” depending on whether the assertion is true, false, or it may be either true or false. (10’)

**Question 1:** $P \subseteq NP$ (5’)

**Question 2:** The knapsack problem is in $P$ (5’)

**Question 3:** The minimal spanning tree problem is in $NP$ (5’)

**Question 4:** $n! = O(n^{100})$ (5’)

**Question 5:** $\sqrt{n} = \Omega(\log(n))$ (5’)

**Question 6:** insertion-sort performs like quicksort on an almost sorted sequence

Exercise 41. An application must read a long sequence of numbers given in no particular order, and perform many searches on that sequence. How would you implement that application to minimize the overall time-complexity? Write exactly what algorithms you would use, and in what sequence. In particular, write the high-level structure of a read function, to read and store the sequence, and a find function too look up a number in the sequence. (10’)

Exercise 42. Write an algorithm that takes a set of $(x,y)$ coordinates representing points on a plane, and outputs the coordinates of two points with the maximal distance. The signature of the algorithm is $\text{Maximal-Distance}(X,Y)$, where $X$ and $Y$ are two arrays of the same length representing the $x$ and $y$ coordinates of each point, respectively. Also, write the asymptotic complexity of $\text{Maximal-Distance}$. Briefly justify your answer. (10’)

Exercise 43. A directed tree is represented as follows: for each vertex $v$, $v.first-child$ is either the first element in a list of child-vertices, or NIL if $v$ is a leaf. For each vertex $v$, $v.next-sibling$ is the next element in the list of $v$’s siblings, or NIL if $v$ is the last element in the list. For example, the arrays on the left represent the tree on the right:

```
1 2 3 4 5 6 7 8 9
f 1 2 3 4 5 6 7 8 9
1 2 3 4 5 6 7 8 9
```

**Question 1:** Write two algorithms, $\text{MAX-DEPTH}(root)$ and $\text{MIN-DEPTH}(root)$, that, given a tree, return the maximal and minimal depth of any leaf vertex, respectively. (E.g., the results for the example tree above are 2 and 1, respectively.) (15’)

**Question 2:** Write an algorithm $\text{DEPTH-FIRST-ORDER}(root)$ that, given a tree, prints the vertices in depth-first visitation order, such that a vertices is always preceded by all its children (e.g., the result for the example tree above is 4, 5, 2, 6, 7, 8, 3, 9, 1). (10’)

**Question 3:** Analyze the complexity of $\text{MAX-DEPTH}$, $\text{MIN-DEPTH}$ and $\text{DEPTH-FIRST-ORDER}$. (5’
Exercise 44. Write an algorithm called \textsc{In-Place-Sort}(A) that takes an array of numbers, and sorts the array \textit{in-place}. That is, using only a constant amount of extra memory. Also, give an informal analysis of the asymptotic complexity of your algorithm.

Exercise 45. Given a sequence \(A = \langle a_1, \ldots, a_n \rangle\) of numbers, the zero-sum-subsequence problem amounts to deciding whether \(A\) contains a subsequence of consecutive elements \(a_i, a_{i+1}, \ldots, a_k\), with \(1 \leq i \leq k \leq n\), such that \(a_i + a_{i+1} + \cdots + a_k = 0\). Model this as a dynamic-programming problem and write a dynamic-programming algorithm \textsc{Zero-SUM-SEQUENCE}(A) that, given an array \(A\), returns \textsc{true} if \(A\) contains a zero-sum subsequence, or \textsc{false} otherwise. Also, give an informal analysis of the complexity of \textsc{Zero-SUM-SEQUENCE}.

Exercise 46. Give an example of a randomized algorithm derived from a deterministic algorithm. Explain why there is an advantage in using the randomized variant.

Exercise 47. Implement a \textsc{Ternary-Tree-Search}(x, k) algorithm that takes the root of a ternary tree and returns the node containing key \(k\). A ternary tree is conceptually identical to a binary tree, except that each node \(x\) has two keys, \(x.key_1\) and \(x.key_2\), and three links to child nodes, \(x.left\), \(x.center\), and \(x.right\), such that the left, center, and right subtrees contains keys that are, respectively, less than \(x.key_1\), between \(x.key_1\) and \(x.key_2\), and greater than \(x.key_2\). Assume there are no duplicate keys. Also, assuming the tree is balanced, what is the asymptotic complexity of the algorithm?

Exercise 48. Answer the following questions. Briefly justify your answers.

Question 1: A hash table that uses chaining has \(M\) slots and holds \(N\) keys. What is the expected complexity of a search operation?

Question 2: The asymptotic complexity of algorithm \(A\) is \(\Omega(N \log N)\), while that of \(B\) is \(\Theta(N^2)\). Can we compare the two algorithms? If so, which one is asymptotically faster?

Question 3: What is the difference between “Las Vegas” and “Monte Carlo” randomized algorithms?

Question 4: What is the main difference between the Knuth-Morris-Pratt algorithm and Boyer-Moore string-matching algorithms in terms of complexity? Which one as the best worst-case complexity?

Exercise 49. A ternary search trie (TST) is used to implement a dictionary of strings. Write the TST corresponding to the following set of strings: “doc” “fun” “algo” “cat” “dog” “data” “car” “led” “function”. Assume the strings are inserted in the given order. Use ‘#’ as the terminator character.

Exercise 50. The following declarations define a ternary search trie in C and Java, respectively:

```c
struct TST {
    char value;
    struct TST * higher;
    struct TST * lower;
    struct TST * equal;
};
void print(const struct TST * t);
```

```java
public class TST {
    byte value;
    TST higher;
    TST lower;
    TST equal;
    void print() {/* ... */}
}
```

The TST represents a dictionary of byte strings. The \texttt{print} method must output all the strings stored in the given TST, in alphabetical order. Assume the terminator value is 0. Write an implementation of the \texttt{print} method, either in C or in Java. You may assume that the TST contains strings of up to 100 characters. (Hint: store the output strings in a static array of characters.)

Exercise 51. Consider \texttt{quick-sort} as an in-place sorting algorithm.

Question 1: Write the pseudo-code using only \texttt{swap} operations to modify the input array.

Question 2: Apply the algorithm of question 1 to the array \(A = \langle 8, 2, 12, 17, 4, 8, 7, 1, 12 \rangle\). Write the content of the array after each swap operation.
Exercise 52. Consider this minimal vertex cover problem: given a graph \( G = (V, E) \), find a minimal set of vertices \( S \) such that for every edge \((u, v) \in E\), \( u \) or \( v \) (or both) are in \( S \).

Question 1: Model minimal vertex cover as a dynamic-programming problem. Write the pseudo-code of a dynamic-programming solution. (15')

Question 2: Do you think that your model of minimal vertex cover admits a greedy choice? Try at least one meaningful greedy strategy. Show that it does not work, giving a counter-example graph for which the strategy produces the wrong result. (Hint: one meaningful strategy is to choose a maximum-degree vertex first. The degree of a vertex is the number of its incident edges.) (5')

Exercise 53. The graph \( G = (V, E) \) represents a social network in which each vertex represents a person, and an edge \((u, v) \in E\) represents the fact that \( u \) and \( v \) know each other. Your problem is to organize the largest party in which nobody knows each other. This is also called the maximal independent set problem. Formally, given a graph \( G = (V, E) \), find a set of vertices \( S \) of maximal size in which no two vertices are adjacent. (I.e., for all \( u \in S \) and \( v \in S \), \((u, v) \not\in E\).)

Question 1: Formulate a decision variant of maximal independent set. Say whether the problem is in NP, and briefly explain what that means. (10')

Question 2: Write a verification algorithm for the maximal independent set problem. This algorithm, called \text{TestIndependentSet}(G, S)\,\,\text{, takes a graph }G\,\,\text{represented through its adjacency matrix, and a set }S\,\,\text{of vertices, and returns }true\,\,\text{if }S\,\,\text{is a valid independent set for }G.\,\,\,(10')

Exercise 54. A Hamilton cycle is a cycle in a graph that touches every vertex exactly once. Formally, in \( G = (V, E) \), an ordering of all vertices \( H = v_1, v_2, \ldots, v_n \) forms a Hamilton cycle if \((v_n, v_1) \in E\,\,\text{, and } (v_i, v_{i+1}) \in E\,\,\text{for all }i\,\,\text{between }1\,\,\text{and }n - 1\). Deciding whether a given graph is Hamiltonian (has a Hamilton cycle) is a well known NP-complete problem.

Question 1: Write a verification algorithm for the Hamiltonian graph problem. This algorithm, called \text{TestHamiltonCycle}(G, H)\,\,\text{, takes a graph }G\,\,\text{represented through adjacency lists, and an array of vertices}\,\,H\,\,\text{, and returns }true\,\,\text{if }H\,\,\text{is a valid Hamilton cycle in }G.\,\,\,\,(10')

Question 2: Give the asymptotic complexity of your implementation of \text{TestHamiltonCycle}.\,\,\,(5')

Exercise 55. Consider using a b-tree with minimum degree \( t = 2 \) as an in-memory data structure to implement dynamic sets.

Question 1: Compare this data structure with a red-black tree. Is this data structure better, worse, or the same as a red-black tree in terms of time complexity? Briefly justify your answer. In particular, characterize the complexity of insertion and search. (10')

Question 2: Write an iterative (i.e., non-recursive) search algorithm for this degree-2 b-tree. Remember that the data structure is in-memory, so there is no need to perform any disk read/write operation. (10')

Question 3: Write the data structure after the insertion of keys 10, 3, 8, 21, 15, 4, 6, 19, 28, 31, in this order, and then after the insertion of keys 25, 33, 7, 1, 23, 35, 24, 11, 2, 5. (10')

Question 4: Write the insertion algorithm for this degree-2 b-tree. (Hint: since the minimum degree is fixed at 2, the insertion algorithm may be implemented in a simpler fashion without all the loops of the full b-tree insertion.) (15')

Exercise 56. Consider a breadth-first search (BFS) on the following graph, starting from vertex \( a \).
Write the two vectors $\pi$ (previous) and $d$ (distance), resulting from the BFS algorithm.

**Exercise 57.** Write a sorting algorithm that runs with in time $O(n \log n)$ in the average case (on an input array of size $n$). Also, characterize the best- and worst-case complexity of your solution.

**Exercise 58.** The following algorithms take an array $A$ of integers. For each algorithm, write the asymptotic, best- and worst-case complexities as functions of the size of the input $n = |A|$. Your characterizations should be as tight as possible. Justify your answers by writing a short explanation of what each algorithm does.

**Algorithm-I**($A$)
1. for $i = |A|$ downto 2
2. $s = TRUE$
3. for $j = 2$ to $i$
5.     swap $A[j - 1] \leftrightarrow A[j]$
6.     $s = FALSE$
7.   if $s == TRUE$
8.      return

**Algorithm-II**($A$)
1. $i = 1$
2. $j = |A|$
3. while $i < j$
5.      swap $A[i] \leftrightarrow A[i + 1]$
6.         if $i + 1 < j$
7.             swap $A[i] \leftrightarrow A[j]$
8.         $i = i + 1$
9.   else $j = j - 1$

**Exercise 59.** The following algorithms take a binary search tree $T$ containing $n$ keys. For each algorithm, write the asymptotic, best- and worst-case complexities as functions of $n$. Your characterizations should be as tight as possible. Justify your answers by writing a short explanation of what each algorithm does.

}\end{verbatim}
Algorithm-III($T, k$)
1. if $T == \text{NIL}$
2. return $\text{FALSE}$
3. if $T$.key == $k$
4. return $\text{TRUE}$
5. if Algorithm-III($T$.left)
6. return $\text{TRUE}$
7. else return Algorithm-III($T$.right)

Algorithm-IV($T, k_1, k_2$)
1. if $T == \text{NIL}$
2. return $0$
3. if $k_1 > k_2$
4. swap $k_1 \leftrightarrow k_2$
5. $r = 0$
6. if $T$.key < $k_2$
7. $r = r + \text{Algorithm-IV}(T$.right, $k_1, k_2$)
8. if $T$.key > $k_1$
9. $r = r + \text{Algorithm-IV}(T$.left, $k_1, k_2$)
10. if $T$.key < $k_2$ and $T$.key > $k_1$
11. $r = r + 1$
12. return $r$

Exercise 60. Answer the following questions on complexity theory. Justify your answers. All problems are decision problems. (Hint: answers are not limited to “yes” or “no.”)

Question 1: An algorithm $A$ solves a problem $P$ of size $n$ in time $O(n^3)$. Is $P$ in $\text{NP}$?

Question 2: An algorithm $A$ solves a problem $P$ of size $n$ in time $\Omega(n \log n)$. Is $P$ in $\text{P}$? Is it in $\text{NP}$?

Question 3: A problem $P$ in $\text{NP}$ can be polynomially reduced into a problem $Q$. Is $Q$ in $\text{P}$? Is $Q$ in $\text{NP}$?

Question 4: A problem $P$ can be polynomially reduced into a problem $Q$ in $\text{NP}$. Is $P$ in $\text{P}$? Is $P$ $\text{NP}$-hard?

Question 5: A problem $P$ of size $n$ does not admit to any algorithmic solution with complexity $O(2^n)$. Is $P$ in $\text{P}$? Is $P$ in $\text{NP}$?

Question 6: An algorithm $A$ takes an instance of a problem $P$ of size $n$ and a “certificate” of size $O(n^c)$, for some constant $c$, and verifies in time $O(n^2)$ that the solution to given problem is affirmative. Is $P$ in $\text{P}$? Is $P$ in $\text{NP}$? Is $P$ $\text{NP}$-complete?

Exercise 61. Write an algorithm $\text{TSTCountGreater}(T, s)$ that takes the root $T$ of a ternary-search trie (TST) and a string $s$, and returns the number of strings stored in the trie that are lexicographically greater than $s$. Given a node $T$, $T$.left, $T$.middle, and $T$.right are the left, middle, and right subtrees, respectively; $T$.value is the value stored in $T$. The TST uses the special character ‘#’ as the string terminator. Given two characters $a$ and $b$, the relation $a < b$ defines the lexicographical order, and the terminator character is less than every other character. (Hint: first write an algorithm that, given a tree (node) counts all the strings stored in that tree.)

Exercise 62. Consider a depth-first search (DFS) on the following graph.
Write the three vectors \( \pi, d, \) and \( f \) that, for each vertex represent the *previous* vertex in the depth-first forest, the *discovery* time, and the *finish* time, respectively. Whenever necessary, iterate through vertexes in alphabetic order.

**Exercise 63.** Write an implementation of a *radix tree* in Java. The tree must store 32-bit integer keys. Each node in the tree must contain at most 256 links or keys, so each node would cover at most 8 bits of the key. You must implement a class called `RadixTree` with two methods, `void insert(int k)` and `boolean find(int k)`. You must also specify every other class you might use. For example, you would probably want to define a class `RadixTreeNode` to represent nodes in the tree.

**Exercise 64.** Answer the following questions about *red-black trees*.

*Question 1:* Describe the structure and the properties of a red-black tree.

*Question 2:* Write an algorithm `RB-TREE-SEARCH(T,k)` that, given a red-black tree \( T \) and a key \( k \), returns \( \text{true} \) if \( T \) contains key \( k \), or \( \text{false} \) otherwise.

*Question 3:* Let \( h \) be the height of a red-black tree containing \( n \) keys, prove that

\[
h \leq 2 \log (n + 1)
\]

*Hint:* first give an outline of the proof. Even if you can not give a complete proof, try to explain informally how the red-black tree property limits the height of a red-black tree.

**Exercise 65.** Sort the following functions in ascending order of asymptotic growth rate:

\[
\begin{align*}
    f_1(n) &= 3^n \\
    f_2(n) &= n^{1/3} \\
    f_3(n) &= \log^2 n \\
    f_4(n) &= n \log n \\
    f_5(n) &= n^3 \\
    f_6(n) &= 4 \log n \\
    f_7(n) &= n^2 \sqrt{n} \\
    f_8(n) &= 2^{2n} \\
    f_9(n) &= \sqrt{\log n}
\end{align*}
\]

That is, write the sequence of sorted indexes \( a_1, a_2, \ldots, a_9 \) such that for all indexes \( a_i, a_j \) with \( i < j, f_{a_i}(n) = O(f_{a_j}(n)) \). (Notice that \( \log n \) means \( \log_2 n \)).

**Exercise 66.** Consider the following algorithm:

```java
ALGO-A(X)
1 \ d = \infty
2 \ for i = 1 to X.length - 1
3 \ \ \ \ for j = i + 1 to X.length
4 \ \ \ \ \ if |X[i] - X[j]| < d
5 \ \ \ \ \ \ \ d = |X[i] - X[j]|
6 \ return d
```
Question 1: Interpreting \( X \) as an array of coordinates of points on the \( x \)-axis, explain concisely what algorithm \textsc{Algo-A} does, and give a tight asymptotic bound for the complexity of \textsc{Algo-A}.

(5')

Question 2: Write an algorithm \textsc{Better-A}(\( X \)) that is functionally equivalent to \textsc{Algo-A}(\( X \)), but with a better asymptotic complexity.

(15')

\begin{itemize}
  \item Exercise 67. The following defines a ternary search trie (TST) for character strings, in Java and in pseudo-code notation:
    \begin{verbatim}
    class TSTNode {
        char c;
        boolean have_key;
        TSTNode left;
        TSTNode middle;
        TSTNode right;
    }
    \end{verbatim}

    Write an algorithm, \texttt{TSTPrint(TSTNode t)} in Java or \texttt{TST-Print(x)} in pseudo-code that, given the root of a TST, prints all its keys in alphabetical order.

    (20')
  \item Exercise 68. A set of keys is stored in a max-heap \( H \) and in a binary search tree \( T \). Which data structure offers the most efficient algorithm to output all the keys in descending order? Or are the two equivalent? Write both algorithms. Your algorithms may change the data structures.

    (20')
  \item Exercise 69. Answer the following questions. Briefly justify your answers.

    \begin{enumerate}
    \item Question 1: Let \( A \) be an array of numbers sorted in descending order. Does \( A \) represent a max-heap (with \( A.\text{heap-size} = A.\text{length} \))?
    \item Question 2: A hash table has \( T \) slots and uses chaining to resolve collisions. What are the worst-case and average-case complexities of a search operation when the hash table contains \( N \) keys?
    \item Question 3: A hash table with 9 slots, uses chaining to resolve collision, and uses the hash function \( h(k) = k \mod 9 \) (slots are numbered \( 0, \ldots, 8 \)). Draw the hash table after the insertion of keys 5, 28, 19, 15, 20, 33, 12, 17, and 10.
    \item Question 4: Is the operation of deletion in a binary search tree commutative in the sense that deleting \( x \) and then \( y \) from a binary search tree leaves the same tree as deleting \( y \) and then \( x \)? Argue why it is or give a counter-example.
    \end{enumerate}

    (10')
  \item Exercise 70. Draw a binary search tree containing keys 8, 27, 13, 15, 32, 20, 12, 50, 29, 11, inserted in this order. Then, add keys 14, 18, 30, 31, in this order, and again draw the tree. Then delete keys 29 and 27, in this order, and again draw the tree.

    (10')
  \item Exercise 71. Consider a max-heap \( H \) and the following algorithm.

    \begin{verbatim}
    BST-FROM-MIN-HEAP(H)
    1    \textbf{T} = NEW-EMPTY-TREE()
    2    \textbf{for } i = 1 \textbf{ to } H.\text{heap-length}
    3    \textbf{Tree-Insert}(T,H[i]) \quad // binary-search-tree insertion
    4    \textbf{return } T
    \end{verbatim}

    Prove that \textsc{BST-FROM-MIN-HEAP} does not always produce minimum-height binary trees.

    (10')
  \item Exercise 72. Consider a min-heap \( H \) and the following algorithm.

    \begin{verbatim}
    BST-FROM-MIN-HEAP(H)
    1    \textbf{T} = NEW-EMPTY-TREE()
    2    \textbf{for } i = 1 \textbf{ to } H.\text{heap-length}
    3    \textbf{Tree-Insert}(T,H[i]) \quad // binary-search-tree insertion
    4    \textbf{return } T
    \end{verbatim}

    Prove that \textsc{BST-FROM-MIN-HEAP} does not always produce minimum-height binary trees.

    (10')
  \item Exercise 73. Consider an array \( A \) containing \( n \) numbers and satisfying the \textit{min-heap} property. Write an algorithm \textsc{Min-Heap-Fast-Search}(\( A,k \)) that finds \( k \) in \( A \) with a time complexity that is better than linear in \( n \) whenever at most \( \sqrt{n} \) of the values in \( A \) are less than \( k \).

    (20')
  \item Exercise 74. Write an algorithm \textsc{B-Tree-Top-K}(\( R,k \)) that, given the root \( R \) of a b-tree of minimum degree \( t \), and an integer \( k \), outputs the largest \( k \) keys in the b-tree. You may assume that the entire b-tree resides in main memory, so no disk access is required. \textit{(Reminder:} a node \( x \) in a b-tree has
the following properties: \( x.n \) is the number of keys, \( X.key[1] \leq x.key[2] \leq \ldots x.key[x.n] \) are the keys, \( x.leaf \) tells whether \( x \) is a leaf, and \( x.c[1], x.c[2], \ldots, x.c[x.n + 1] \) are the pointers to \( x \)'s children.

**Exercise 75.** Your computer has a special machine instruction called \( \text{SORT-FIVE}(A, i) \) that, given an array \( A \) and a position \( i \), sorts in-place and in a single step the elements \( A[i \ldots i+5] \) (or \( A[i \ldots |A|] \) if \( |A| < i + 5 \)). Write an in-place sorting algorithm called \( \text{SORT-WITH-SORT-FIVE} \) that uses only \( \text{SORT-FIVE} \) to modify the array \( A \). Also, analyze the complexity of \( \text{SORT-WITH-SORT-FIVE} \).

**Exercise 76.** For each of the following statements, briefly argue why they are true, or show a counter-example.

*Question 1:* \( f(n) = O(n!) \Rightarrow \log(f(n)) = O(n \log n) \)

*Question 2:* \( f(n) = \Theta(f(n/2)) \)

*Question 3:* \( f(n) + g(n) = \Theta(\min(f(n), g(n))) \)

*Question 4:* \( f(n)g(n) = O(\max(f(n), g(n))) \)

*Question 5:* \( f(g(n)) = \Omega(\min(f(n), g(n))) \)

**Exercise 77.** Characterize the complexity of the following algorithm. Briefly justify your answer.

```python
SHUFFLE-A-BIT(A)
1  i = 1
2  j = A.length
3  while j > i
4      p = CHOOSE-UNFORMLY([0, 1])
5      if p == 1
7      j = j - 1
8      i = i + 1
9  SHUFFLE-A-BIT(A[1...j])
10 SHUFFLE-A-BIT(A[i...A.length])
```

**Exercise 78.** Answer the following questions. For each question, write “yes” when the answer is always true, “no” when it is always false, “undefined” when it can be true or false.

*Question 1:* Algorithm \( A \) solves decision problem \( X \) in time \( O(n \log n) \). Is \( X \) in \( \text{NP} \)?

*Question 2:* Is \( X \) in \( \text{P} \)?

*Question 3:* Decision problem \( X \) in \( \text{P} \) can be polynomially reduced to problem \( Y \). Is there a polynomial-time algorithm to solve \( Y \)?

*Question 4:* Decision problem \( X \) can be polynomially reduced to a problem \( Y \) for which there is a polynomial-time verification algorithm. Is \( X \) in \( \text{NP} \)?

*Question 5:* Is \( X \) in \( \text{P} \)?

*Question 6:* An \( \text{NP-hard} \) decision problem \( X \) can be polynomially reduced to problem \( Y \). Is \( Y \) in \( \text{NP} \)?

*Question 7:* Is \( Y \) \( \text{NP-hard} \)?

*Question 8:* Algorithm \( A \) solves decision problem \( X \) in time \( \Theta(2^n) \). Is \( X \) in \( \text{NP} \)?

*Question 9:* Is \( X \) in \( \text{P} \)?

**Exercise 79.** Write a minimal character-based binary code for the following sentence:

\[ \text{in theory, there is no difference between theory and practice; in practice, there is.} \]

The code must map each character, including spaces and punctuation marks, to a binary string so that the total length of the encoded sentence is minimal. Use a Huffman code and show the derivation of the code.
**Exercise 80.** The following matrix represents a directed graph over 12 vertices labeled \(a, b, \ldots, \ell\). Rows and columns represent the source and destination of edges, respectively. For example, the value 1 in row \(a\) and column \(f\) indicates an edge from \(a\) to \(f\).

\[
\begin{array}{cccccccccc}
& a & b & c & d & e & f & g & h & i & j & k & \ell \\
\hline
a & 1 & & & & & & & & & & & \\
b & 1 & 1 & 1 & & & & & & & & & \\
c & & 1 & 1 & & & & & & & & & \\
d & 1 & 1 & 1 & & & & & & & & & \\
e & & 1 & 1 & 1 & & & & & & & & \\
f & 1 & & & 1 & 1 & & & & & & & \\
g & & 1 & 1 & & & & & & & & & \\
h & 1 & 1 & & & & & & & & & & \\
i & & & & & & & & 1 & & & & \\
j & 1 & & & 1 & & & & & & & & \\
k & 1 & & & 1 & & & & & & & & \\
\ell & & & & & & & & & & & & 1 & 1 \\
\end{array}
\]

Run a **breadth-first search** on the graph starting from vertex \(a\). Using the table below, write the two vectors \(\pi\) (previous) and \(d\) (distance) at each main iteration of the BFS algorithm. Write the pair \(\pi, d\) in each cell; for each iteration, write only the values that change. Also, write the complete BFS tree after the termination of the algorithm. (20’)

<table>

**Exercise 81.** A **graph coloring** associates a color with each vertex of a graph so that adjacent vertices have different colors. Write a greedy algorithm that tries to color a given graph with the least number of colors. This is a well known and difficult problem for which, most likely, there is no perfect greedy strategy. So, you should use a reasonable strategy, and it is okay if your algorithm does not return the absolute best coloring. The result must be a **color** array, where \(v.color\) is a number representing the color of vertex \(v\). Write the algorithm, analyze its complexity, and also show an example in which the algorithm does not achieve the best possible result. (20’)

**Exercise 82.** Given an array \(A\) and a positive integer \(k\), the **selection** problem amounts to finding the largest element \(x \in A\) such that at most \(k\) elements of \(A\) are less than or equal to \(x\), or NIL if no such element exists. A simple way to implement it is as follows:

```
SIMPLESELECTION(A, k)
1 if k > A.length
2 return NIL
3 else sort A in ascending order
4 return A[k]
```

Write another algorithm that solves the selection problem without first sorting \(A\). (Hint: use a divide-and-conquer strategy that “divides” \(A\) using one of its elements.) Also, illustrate the execution of the algorithm on the following input by writing its state at each main iteration or recursion.

\(A = \langle 29, 28, 35, 20, 9, 33, 8, 9, 11, 6, 21, 28, 18, 36, 1 \rangle\) \hspace{1cm} \(k = 6\) (20’)

**Exercise 83.** Consider the following **maximum-value contiguous subsequence** problem: given a sequence of numbers \(A = \langle a_1, a_2, \ldots, a_n \rangle\), find two positions \(i\) and \(j\), with \(1 \leq i \leq j \leq n\), such that the sum \(a_i + a_{i+1} + \cdots + a_j\) is maximal.
Question 1: Write an algorithm to solve the problem and analyze its complexity.

Question 2: If you have not already done so for question 1, write an algorithm that solves the maximum-value contiguous subsequence problem in time $O(n)$. (Hint: one such algorithm uses dynamic-programming.)

Exercise 84. Consider the following intuitive definition of the size of a binary search (sub)tree $t$:

$$\text{size}(t) = 0 \text{ if } t \text{ is NIL, or size}(t) = 1 + \text{size}(t.e) + \text{size}(t.r) \text{ otherwise.}$$

For each node $t$ in a tree, let attribute $t.size$ denote the size of the subtree rooted at $t$.

Question 1: Prove that, if for each node $t$ in a tree $T$, $\max\{\text{size}(t.e), \text{size}(t.r)\} \leq \frac{2}{3}\text{size}(t)$, then the height of $T$ is $O(\log n)$, where $n = \text{size}(T)$.

Question 2: Write the rotation procedures \text{ROTATE-LEFT}(t)$ and \text{ROTATE-RIGHT}(t)$ that return the left- and right rotation of tree $t$ maintaining the correct size attributes.

Question 3: Write an algorithm called \text{SELECTION}(T, i)$ that, given a tree $T$ where each node $t$ carries its size in $t.size$, returns the $i$-th key in $T$.

Question 4: A tree $T$ is perfectly balanced when $\max\{\text{size}(t.e), \text{size}(t.r)\} = \lfloor \text{size}(t)/2 \rfloor$ for all nodes $t \in T$. Write an algorithm called \text{BALANCE}(T)$ that, using the rotation procedures defined in question 2, balances $T$ perfectly. (Hint: the essential operation is to move the median value of a subtree to the root of that subtree.)

Exercise 85. Write the \text{heap-sort} algorithm and illustrate its execution on the following sequence.

$$A = \{1, 1, 24, 8, 3, 36, 34, 23, 4, 30\}$$

Assuming the sequence $A$ is stored in an array passed to the algorithm, for each main iteration (or recursion) of the algorithm, write the content of the array.

Exercise 86. A radix tree is used to represent a dictionary of words defined over the alphabet of the 26 letters of the English language. Assume that letters from A to Z are represented as numbers from 1 to 26. For each node $x$ of the tree, $x.links$ is the array of links to other nodes, and $x.value$ is a Boolean value that is true when $x$ represents a word in the dictionary. Write an algorithm \text{PRINT-RADIX-TREE}(T)$ that outputs all the words in the dictionary rooted at $T$.

Exercise 87. Consider the following algorithm that takes an array $A$ of length $A.length$:

```
ALGO-X(A)
1 for i = 3 to A.length
2   for j = 2 to i - 1
3     for k = 1 to j - 1
7     return TRUE
8 return FALSE
```

Write an algorithm \text{BETTER-ALGO-X}(A)$ equivalent to \text{ALGO-X}(A)$ (for all $A$) but with a strictly better asymptotic complexity than \text{ALGO-X}(A)$.

Exercise 88. For each of the following statements, write whether it is correct or not. Justify your answer by briefly arguing why it is correct, or otherwise by giving a counter example.

Question 1: If $f(n) = O(g^2(n))$ then $f(n) = \Omega(g(n))$.

Question 2: If $f(n) = \Theta(2^n)$ then $f(n) = \Theta(3^n)$.

Question 3: If $f(n) = O(n^3)$ then $\log(f(n)) = O(\log n)$.

Question 4: $f(n) = \Theta(f(2n))$

Question 5: $f(2n) = \Omega(f(n))$

Exercise 89. Write an algorithm \text{PARTITION}(A, k)$ that, given an array $A$ of numbers and a value $k$, changes $A$ in-place by only swapping two of its elements at a time so that all elements that are less than or equal to $k$ precede all other elements.
Exercise 90. Consider an initially empty B-Tree with minimum degree \( t = 2 \).

**Question 1:** Draw the tree after the insertion of keys 81, 56, 16, 31, 50, 71, 58, 83, 0, and 60 in this order.

**Question 2:** Can a different insertion order produce a different tree? If so, write the same set of keys in a different order and the corresponding B-Tree. If not, explain why.

(10')

Exercise 91. Consider the following decision problem. Given a set of integers \( A \), output 1 if some of the numbers in \( A \) add up to a multiple of 10, or 0 otherwise.

**Question 1:** Is this problem in NP? If it is, then write a corresponding verification algorithm. If not, explain why not.

(5')

**Question 2:** Is this problem in P? If it is, then write a polynomial-time solution algorithm. Otherwise, argue why not. (Hint: consider the input values modulo 10. That is, for each input value, consider the remainder of its division by 10.)

(15')

Exercise 92. The following greedy algorithm is intended to find the shortest path between vertices \( u \) and \( v \) in a graph \( G = (V, E, w) \), where \( w(x, y) \) is the length of edge \( (x, y) \in E \).

```
GREEDY-SHORTEST-PATH(G = (V, E, w), u, v)
1   Visited = {u}        // this is a set
2   path = ⟨u⟩          // this is a sequence
3   while path not empty
4       x = last vertex in path
5           if x == v
6               return path
7       y = vertex y ∈ Adj[x] such that y ∈ Visited and w(x, y) is minimal
8           // y is x’s closest neighbor not already visited
9               path = path − ⟨x⟩      // removes the last element y from path
10          else Visited = Visited ∪ {y}
11             path = path + ⟨y⟩      // append y to path
12        return undefined        // there is no path between u and v
```

Does this algorithm find the shortest path always, sometimes, or never? If it always works, then explain its correctness by defining a suitable invariant for the main loop, or explain why the greedy choice is correct. If it works sometimes (but not always) show a positive example and a negative example, and briefly explain why the greedy choice does not work. If it is never correct, show an example and briefly explain why the greedy choice does not work.

(20')

Exercise 93. Write the quick-sort algorithm as a deterministic in-place algorithm, and then apply it to the array

\[
\langle 50, 47, 92, 78, 76, 7, 60, 36, 59, 30, 50, 43 \rangle
\]

Show the application of the algorithm by writing the content of the array after each main iteration or recursion.

(20')

Exercise 94. Consider an undirected graph \( G \) of \( n \) vertices represented by its adjacency matrix \( A \). Write an algorithm called IS-CYCICAL(A) that, given the adjacency matrix \( A \), returns true if \( G \) contains a cycle, or false if \( G \) is acyclic. Also, give a precise analysis of the complexity of your algorithm.

(20')

Exercise 95. A palindrome is a sequence of characters that is identical when read left-to-right and right-to-left. For example, the word “racecar” is a palindrome, as is the phrase “rats live on no evil star.” Write an algorithm called LONGEST-PALINDROME(T) that, given an array of characters \( T \), prints the longest palindrome in \( T \), or any one of them if there are more than one. For example, if \( T \) is the text “radar radiations” then your algorithm should output “dar rad”. Also, give a precise analysis of the complexity of your algorithm.

(20')
Exercise 96. Write an algorithm called occurrences that, given an array of numbers $A$, prints all the distinct values in $A$ each followed by its number of occurrences. For example, if $A = \langle 28, 1, 0, 1, 0, 3, 4, 0, 0, 3 \rangle$, the algorithm should output the following five lines (here separated by a semicolon) “28 1; 1 2; 0 4; 3 2; 4 1”. The algorithm may modify the content of $A$, but may not use any other memory. Each distinct value must be printed exactly once. Values may be printed in any order. The complexity of the algorithm must be $o(n^2)$, that is, strictly lower than $O(n^2)$.

Exercise 97. The following algorithm takes an array of line segments. Each line segment $s$ is defined by its two end-points $s.a$ and $s.b$, each defined by their Cartesian coordinates $(s.a.x, s.a.y)$ and $(s.b.x, s.b.y)$, respectively, and ordered such that either $s.a.x < s.b.x$ or $s.a.x = s.b.x$ and $s.a.y < s.b.y$. That is, $s.b$ is never to the left of $s.a$, and if $s.a$ and $s.b$ have the same $x$ coordinates, then $s.a$ is below $s.b$.

EQUALS($p, q$)  
// tests whether $p$ and $q$ are the same point
1 if $p.x == q.x$ and $p.y == q.y$
2 return TRUE
3 else return FALSE

ALGO-X($A$)
1 for $i = 1$ to $A.length$
2 for $j = 1$ to $A.length$
3 if EQUALS($A[i].a, A[j].a$)
4 for $k = 1$ to $A.length$
5 if EQUALS($A[j].b, A[k].b$) and EQUALS($A[i].a, A[k].a$)
6 return TRUE
7 return FALSE

Question 1: Analyze the asymptotic complexity of ALGO-X

Question 2: Write an algorithm ALGO-Y that does exactly what ALGO-X does but with a better asymptotic complexity. Also, write the asymptotic complexity of ALGO-Y.

Exercise 98. Write an algorithm called TREE-TO-VINE that, given a binary search tree $T$, returns the same tree changed into a vine, that is, a tree containing exactly the same nodes but restructured so that no node has a left child (i.e., the returned tree looks like a linked list). The algorithm must not destroy or create nodes or use any additional memory other than what is already in the tree, and therefore must operate through a sequence of rotations. Write explicitly all the rotation algorithms used in TREE-TO-VINE. Also, analyze the complexity of TREE-TO-VINE.

Exercise 99. We say that a binary tree $T$ is perfectly balanced if, for each node $n$ in $T$, the number of keys in the left and right subtrees of $n$ differ at most by 1. Write an algorithm called IS-PERFECTLY-BALANCED that, given a binary tree $T$ returns TRUE if $T$ is perfectly balanced, and FALSE otherwise. Also, analyze the complexity of IS-PERFECTLY-BALANCED.

Exercise 100. Two graphs $G$ and $H$ are isomorphic if there exists a bijection $f : V(G) \rightarrow V(H)$ between the vertexes of $G$ and $H$ (i.e., a one-to-one correspondence) such that any two vertices $u$ and $v$ in $G$ are adjacent (in $G$) if and only if $f(u)$ and $f(v)$ are adjacent in $H$. The graph-isomorphism problem is the problem of deciding whether two given graphs are isomorphic.

Question 1: Is graph isomorphism in NP? If so, explain why and write a verification procedure. If not, argue why not.

Question 2: Consider the following algorithm to solve the graph-isomorphism problem:
ISOMORPHIC(G,H)
1 if |V(G)| \neq |V(H)|
2 return FALSE
3 A = V(G) sorted by degree  // A is a sequence of the vertices of G
4 B = V(H) sorted by degree  // B is a sequence of the vertices of H
5 for i = 1 to |V(G)|
6 if degree(A[i]) \neq degree(B[i])
7 return FALSE
8 return TRUE

Is ISOMORPHIC correct? If so, explain at a high level what the algorithm does and informally but precisely why it works. If not, show a counter-example.

**Exercise 101.** Write an algorithm HEAP-PRINT-IN-ORDER(H) that takes a min heap H containing unique elements (no element appears twice in H) and prints the elements of H in increasing order. The algorithm must not modify H and may only use a constant amount of additional memory. Also, analyze the complexity of HEAP-PRINT-IN-ORDER.

**Exercise 102.** Write an algorithm BST-RANGE-WEIGHT(T,a,b) that takes a well balanced binary search tree T (or more specifically the root T of such a tree) and two keys a and b, with a \leq b, and returns the number of keys in T that are between a and b. Assuming there are o(n) such keys, then the algorithm should have a complexity of o(n), that is, strictly better than linear in the size of the tree. Analyze the complexity of BST-RANGE-WEIGHT.

**Exercise 103.** Let (a,b) represent an interval (or range) of values x such that a \leq x \leq b. Consider an array X = \langle a_1,b_1,a_2,b_2,...,a_n,b_n \rangle of 2n numbers representing n intervals \langle a_i,b_i \rangle, where a_i = X[2i-1] and b_i = X[2i] and a_i \leq b_i. Write an algorithm called SIMPLIFY-INTERVALS(X) that takes an array X representing n intervals, and simplifies X in-place. The “simplification” of a set of intervals X is a minimal set of intervals representing the union of all the intervals in X. Notice that the union of two disjoint intervals can not be simplified, but the union of two partially overlapping intervals can be simplified into a single interval. For example, a correct solution for the simplification of X = \langle 3,7,1,5,10,12,6,8 \rangle is X = \langle 10,12,1,8 \rangle. An array X can be shrunk by setting its length (effectively removing elements at the end of the array). In this example, X.length should be 4 after the execution of the simplification algorithm. Analyze the complexity of SIMPLIFY-INTERVALS.

**Exercise 104.** Write an algorithm SIMPLIFY-INTERVALS-FAST(X) that solves exercise 103 with a complexity of O(n log n). If your solution for exercise 103 already has an O(n log n) complexity, then simply say so.

**Exercise 105.** Consider the following algorithm:

\[\text{ALGO-X}(A,k)\]
1 \hspace{1em} i = 1
2 \hspace{1em} while i \leq A.length
3 \hspace{1em} if A[i] = k
4 \hspace{1em} ALGO-Y(A, i)
5 \hspace{1em} else i = i + 1

\[\text{ALGO-Y}(A, i)\]
1 \hspace{1em} while i < A.length
2 \hspace{1em} A[i] = A[i + 1]
3 \hspace{1em} i = i + 1

Analyze the complexity of ALGO-X and write an algorithm called BETTER-ALGO-X that does exactly the same thing, but with a strictly better asymptotic complexity. Analyze the complexity of BETTER-ALGO-X.

**Exercise 106.** Write an in-place partition algorithm called MODULO-PARTITION(A) that takes an array A of n numbers and changes A in such a way that (1) the final content of A is a permutation of the initial content of A, and (2) all the values that are equivalent to 0 mod 10 precede all the values equivalent to 1 mod 10, which precede all the values equivalent to 2 mod 10, etc. Being an in-place algorithm, MODULO-PARTITION must not allocate more than a constant amount of memory. For example, for an input array A = \langle 7,6,2,5,5,12,39,5,8,16,48 \rangle, a correct result would be A = \langle 12,62,5,5,16,57,7,8,48,39 \rangle. Analyze the complexity of MODULO-PARTITION.
Exercise 107. Write the merge sort algorithm and analyze its complexity.

Exercise 108. Write an algorithm called LONGEST-REPEATED-SUBSTRING(T) that takes a string T representing some text, and finds the longest string that occurs at least twice in T. The algorithm returns three numbers begin1, end1, and begin2, where begin1 \leq end1 represent the first and last position of the longest substring of T that also occurs starting at another position begin1 \neq begin2 in T. If no such substring exist, then the algorithm returns “None.” Analyze the time and space complexity of your algorithm.

Exercise 109. Answer the following questions on complexity theory. Reminder: SAT is the Boolean satisfiability problem, which is a well-known NP-complete problem.

Question 1: A decision problem Q is polynomially-reducible to SAT. Can we say for sure that Q is NP-complete?

Question 2: SAT is polynomially-reducible to a decision problem Q. Can we say for sure that Q is NP-complete?

Question 3: A decision problem Q is polynomially reducible to a problem Q’ and Q’ is polynomially reducible to SAT. Can we say for sure that Q is in NP?

Question 4: An algorithm A solves every instance of a decision problem Q of size n in O(n^3) time. Also, Q is polynomially reducible to another problem Q’. Can we say for sure that Q’ is in NP?

Question 5: A decision problem Q is polynomially reducible to another decision problem Q’, and an algorithm A solves Q’ with complexity O(n log n). Can we say for sure that Q is in NP?

Question 6: Consider the following decision problem Q: given a graph G, output 1 if G is connected (i.e., there exists a path between each pair of vertices) or 0 otherwise. Is Q in P? If so, outline an algorithm that proves it, if not argue why not.

Question 7: Consider the following decision problem Q: given a graph G and an integer k, output 1 if G contains a cycle of size k. Is Q in NP? If so, outline an algorithm that proves it, if not argue why not.

Exercise 110. Consider an initially empty B-tree with minimum degree t = 3. Draw the B-tree after the insertion of the keys 84, 13, 36, 91, 98, 14, 81, 95, 12, 63, 31, and then after the additional insertion of the keys 65, 62, 187, 188, 57, 127, 6, 195, 25.

Exercise 111. Write an algorithm B-TREE-RANGE(T, k1, k2) that takes a B-tree T and two keys k1 \leq k2, and prints all the keys in T between k1 and k2 (inclusive).

Exercise 112. Write an algorithm called FIND-TRIANGLE(G) that takes a graph represented by its adjacency list G and returns true if G contains a triangle. A triangle in a graph G is a triple of vertices u, v, w such that all three edges (u, v), (v, w), and (u, w) are in G. Analyze the complexity of FIND-TRIANGLE.

Exercise 113. Write an algorithm MIN-HEAP-INSERT(H, k) that inserts a key k in a min-heap H. Also, illustrate the algorithm by writing the content of the array H after the insertion of keys 84, 13, 36, 91, 98, 14, 81, 95, 12, 63, 31, and then after the additional insertion of the key 15.

Exercise 114. Implement a priority queue by writing two algorithms:

- ENQUEUE(Q, x, p) enqueues an object x with priority p, and
- DEQUEUE(Q) extracts and returns an object from the queue.

The behavior of ENQUEUE and DEQUEUE is such that, if a call ENQUEUE(Q, x1, p1) is followed (not necessarily immediately) by another call ENQUEUE(Q, x2, p2), then x1 is dequeued before x2 unless p2 > p1. Implement ENQUEUE and DEQUEUE such that their complexity is o(n) for a queue of n elements (i.e., strictly less than linear).

Exercise 115. Write an algorithm called MAX-HEAP-MERGE-NEW(H1, H2) that takes two max-heaps H1 and H2, and returns a new max-heap that contains all the elements of H1 and H2. MAX-HEAP-MERGE-NEW must create a new max heap, therefore it must allocate a new heap H and somehow copy all the elements from H1 and H2 into H without modifying H1 and H2. Also, analyze the complexity of MAX-HEAP-MERGE-NEW.
Exercise 116. Write an algorithm called BST-MERGE-INPLACE\((T_1, T_2)\) that takes two binary-search trees \(T_1\) and \(T_2\), and returns a new binary-search tree by merging all the elements of \(T_1\) and \(T_2\). BST-MERGE-INPLACE is in-place in the sense that it must rearrange the nodes of \(T_1\) and \(T_2\) in a single binary-search tree without creating any new node. Also, analyze the complexity of BST-MERGE-INPLACE.

Exercise 117. Let \(A\) be an array of points in the 2D Euclidean space, each with its Cartesian coordinates \(A[i].x\) and \(A[i].y\). Write an algorithm MINIMUM-BOUNDING-RECTANGLE\((A)\) that, given an array \(A\) of \(n\) points, in \(O(n)\) time returns the smallest axis-aligned rectangle that contains all the points in \(A\). MINIMUM-BOUNDING-RECTANGLE must return a pair of points corresponding to the bottom-left and top-right corners of the rectangle, respectively.

Exercise 118. Let \(A\) be an array of points in the 2D Euclidean space, each with its Cartesian coordinates \(A[i].x\) and \(A[i].y\). Write an algorithm LARGEST-CLUSTER\((A, \ell)\) that, given an array \(A\) of points and a length \(\ell\), returns the maximum number of points in \(A\) that are contained in a square of size \(\ell\). Also, analyze the complexity of LARGEST-CLUSTER.

Exercise 119. Consider the following algorithm that takes an array of numbers:

ALGO-X\((A)\)
1. \(i = 1\)
2. \(j = 1\)
3. \(m = 0\)
4. \(c = 0\)
5. while \(i \leq |A|\)
6. \(\text{if } A[i] = A[j]\)
7. \(\quad c = c + 1\)
8. \(\quad j = j + 1\)
9. \(\text{if } j > |A|\)
10. \(\quad \text{if } c > m\)
11. \(\quad \quad m = c\)
12. \(\quad c = 0\)
13. \(\quad i = i + 1\)
14. \(\quad j = i\)
15. return \(m\)

Question 1: Analyze the complexity of ALGO-X.

Question 2: Write an algorithm that does exactly the same thing as ALGO-X but with a strictly better asymptotic time complexity.

Exercise 120. Write a THREE-WAY-MERGE\((A, B, C)\) algorithm that merges three sorted sequences into a single sorted sequence, and use it to implement a THREE-WAY-MERGE-SORT\((L)\) algorithm. Also, analyze the complexity of THREE-WAY-MERGE-SORT.

Exercise 121. Write an algorithm IS-SIMPLE-POLYGON\((A)\) that takes a sequence \(A\) of 2D points, where each point \(A[i]\) is defined by its Cartesian coordinates \(A[i].x\) and \(A[i].y\), and returns \(TRUE\) if \(A\) defines a simple polygon, or \(FALSE\) otherwise. Also, analyze the complexity of IS-SIMPLE-POLYGON. A polygon is simple if its line segments do not intersect.

Example:

\[
\text{IS-SIMPLE-POLYGON}(A) = \text{TRUE} \quad \text{IS-SIMPLE-POLYGON}(A) = \text{FALSE}
\]
Hint: Use the following DIRECTION-ABC algorithm to determine whether a point $c$ is on the left side, collinear, or on the right side of a segment $ab$:

DIRECTION-ABC($a, b, c$)

1. $d = (b.x - a.x)(c.y - a.y) - (b.y - a.y)(c.x - a.x)$
2. if $d > 0$
   3. return LEFT
3. elseif $d == 0$
   4. return CO-LINEAR
4. else return RIGHT

Example:

$$DIRECTION-ABC(a, b, c) = \text{LEFT}$$

Exercise 122. Implement a dictionary that supports longest prefix matching. Specifically, write the following algorithms:

- BUILD-DICTIONARY($W$) takes a list $W$ of $n$ strings and builds the dictionary.
- LONGEST-PREFIX($k$) takes a string $k$ and returns the longest prefix of $k$ found in the dictionary, or NULL if none exists. The time complexity of LONGEST-PREFIX($k$) must be $o(n)$, that is, sublinear in the size $n$ of the dictionary.

For example, assuming the dictionary was built with strings, “luna”, “lunatic”, “a”, “al”, “algo”, “an”, “anto”, then if $k$ is “algorithms”, then LONGEST-PREFIX($k$) should return “algo”, or if $k$ is “anarchy” then LONGEST-PREFIX($k$) should return “an”, or if $k$ is “lugano” then LONGEST-PREFIX($k$) should return NULL.

Exercise 123. Consider the following decision problem: given a set $S$ of character strings, with characters of a fixed alphabet (e.g., the Roman alphabet), and given an integer $k$, return TRUE if there are at least $k$ strings in $S$ that have a common substring.

Question 1: Is the problem in NP? Write an algorithm that proves it is, or argue the opposite.

Question 2: Is the problem in P? Write an algorithm that proves it is, or argue the opposite.

Exercise 124. Draw a red-black tree containing the following set of keys, clearly indicating the color of each node.

$$\{8, 7, 7, 35, 23, 35, 13, 7, 23, 18, 3, 19, 22\}$$

Exercise 125. Consider the following algorithm ALGO-X that takes an array $A$ of $n$ numbers:

ALGO-X($A$)

1. return ALGO-XR($A, 0, 1, 2$)

ALGO-XR($A, t, i, r$)

1. while $i \leq A.length$
2. if $r == 0$
3. if $A[i] == t$
4. return TRUE
5. else if ALGO-XR($A, t - A[i], i + 1, r - 1$)
6. return TRUE
7. $i = i + 1$
8. return FALSE

Analyze the complexity of ALGO-X and then write an algorithm BETTER-ALGO-X that does exactly the same thing but with a strictly better time complexity.

Exercise 126. A Eulerian cycle in a graph is a cycle that goes through each edge exactly once. As it turns out, a graph contains a Eulerian cycle if (1) it is connected, and (2) all its vertexes have even degree. Write an algorithm EULERIAN($G$) that takes a graph $G$ represented as an adjacency matrix, and returns TRUE when $G$ contains a Eulerian cycle.
Exercise 127. Consider a social network system that, for each user $u$, stores $u$’s friends in a list $\text{friends}(u)$. Implement an algorithm $\text{Top-Three-Friends-Of-Friends}(u)$ that, given a user $u$, recommends the three other users that are not already among $u$’s friends but are among the friends of most of $u$’s friends. Also, analyze the complexity of the $\text{Top-Three-Friends-Of-Friends}$ algorithm.

Exercise 128. Consider the following algorithm:

```
ALGO-X(A)
1 for i = 3 to A.length
2 for j = 2 to i - 1
3 for k = 1 to j - 1
4 x = A[i]
5 y = A[j]
6 z = A[k]
7 if x > y
8 swap x ← y
9 if y > z
10 swap y ← z
11 if x > y
12 swap x ← y
13 if y - x == z - y
14 return TRUE
15 return FALSE
```

Analyze the complexity of $\text{ALGO-X}$ and write an algorithm called $\text{Better-ALGO-X}(A)$ that does the same as $\text{ALGO-X}(A)$ but with a strictly better asymptotic time complexity and with the same space complexity.

Exercise 129. The weather service stores the daily temperature measurements for each city as vectors of real numbers.

Question 1: Write an algorithm called $\text{Hot-Days}(A, t)$ that takes an array $A$ of daily temperature measurements for a city and a temperature $t$, and returns the maximum number of consecutive days with a recorded temperature above $t$. Also, analyze the complexity of $\text{Hot-Days}(A, t)$.

Question 2: Now imagine that a particular analysis would call the $\text{Hot-Days}$ algorithm several times with the same series $A$ of temperature measurements (but with different temperature values) and therefore it would be more efficient to somehow index or precompute the results. To do that, write the following two algorithms:

- A preprocessing algorithm called $\text{Hot-Days-Init}(A)$ that takes the series of temperature measurements $A$ and creates an auxiliary data structure $X$ (an index of some sort).
- An algorithm called $\text{Hot-Days-Fast}(X, t)$ that takes the index $X$ and a temperature $t$ and returns the maximum number of consecutive days with a temperature above $t$. $\text{Hot-Days-Fast}$ must run in sub-linear time in the size of $A$.

Also, analyze the complexity of $\text{Hot-Days-Init}$ and $\text{Hot-Days-Fast}$.

Exercise 130. Consider the following decision problem: given a sequence $A$ of numbers and given an integer $k$, return $\text{TRUE}$ if $A$ contains either an increasing or a decreasing subsequence of length $k$. The elements of the subsequence must maintain their order in $A$ but do not have to be contiguous.

Question 1: Is the problem in NP? Write an algorithm that proves it is, or argue the opposite.

Question 2: Is the problem in P? Write an algorithm that proves it is, or argue the opposite.

Exercise 131. Write an algorithm $\text{Heap-Delete}(H, i)$ that, given a max-heap $H$, deletes the element at position $i$ from $H$. 

Exercise 132.
Exercise 132. Write an algorithm MAX-CLUSTER(A, d) that takes an array A of numbers (not necessarily integers) and a number d, and prints a maximal set of numbers in A that differ by at most d. The output can be given in any order. Your algorithm must have a complexity that is strictly better than \(O(n^2)\). For example, with

\[ A = (7, 15, 16, 3, 10, 43, 8, 1, 29, 13, 4.5, 28) \quad d = 5 \]

MAX-CLUSTER(A, d) would output 7, 3, 4.5, 8 (or the same numbers in any other order) since those numbers differ by at most 5 and there is no larger set of numbers in A that differ by at most 5. Also, analyze the complexity of MAX-CLUSTER.

Exercise 133. Consider the following algorithm that takes a non-empty array of numbers

\[
\text{ALGO-X}(A) \\
1 \quad B = \text{make a copy of } A \\
2 \quad i = 1 \\
3 \quad \text{while } i \leq B.\text{length} \\
4 \quad \quad j = i + 1 \\
5 \quad \text{while } j \leq B.\text{length} \\
6 \quad \quad \text{if } B[j] == B[i] \\
7 \quad \quad \quad i = i + 1 \\
8 \quad \quad \text{swap } B[i] \leftrightarrow B[j] \\
9 \quad \quad j = j + 1 \\
10 \quad i = i + 1 \\
11 \quad q = B[1] \\
12 \quad n = 1 \\
13 \quad m = 1 \\
14 \quad \text{for } i = 2 \text{ to } B.\text{length} \\
15 \quad \quad \text{if } B[i] == q \\
16 \quad \quad \quad n = n + 1 \\
17 \quad \quad \text{if } n > m \\
18 \quad \quad \quad m = m + 1 \\
19 \quad \quad \text{else } q = B[i] \\
20 \quad \quad n = 1 \\
21 \quad \text{return } m
\]

Question 1: Briefly explain what ALGO-X does, and analyze the complexity of ALGO-X. Question 2: Write an algorithm called BETTER-ALGO-X that is functionally identical to ALGO-X but with a strictly better complexity. Analyze the complexity of BETTER-ALGO-X.

Exercise 134. Write the heap-sort algorithm and then illustrate how heap-sort processes the following array in-place:

\[ A = (33, 28, 23, 48, 32, 46, 40, 12, 21, 41, 14, 37, 38, 0, 25) \]

In particular, show the content of the array at each main iteration of the algorithm.

Exercise 135. Write an algorithm BST-PRINT-LONGEST-PATH(T) that, given a binary search tree T, outputs the sequence of nodes (values) of the path from the root to any node of maximal depth. Also, analyze the complexity of BST-PRINT-LONGEST-PATH.

Exercise 136. Consider insertion in a binary search tree.

Question 1: Write a valid insertion algorithm BST-INSERT.

Question 2: Illustrate how BST-INSERT works by drawing the binary search tree resulting from the insertion of the following keys in this order:

\[ 33, 28, 23, 48, 32, 46, 40, 12, 21, 41, 14, 37, 38, 0, 25 \]

Also, if the resulting tree is not already of minimal depth, write an alternative insertion order that would result in a tree of minimal depth.
**Question 3:** Write an algorithm \textsc{Best-BST-Insert-Order}(A) that takes an array of numbers \(A\) and outputs the elements of \(A\) in an order that, if used with \textsc{BST-Insert} would lead to a binary search tree of minimal depth.

**Exercise 137.** Write an algorithm called \textsc{Find-Negative-Cycle} that, given a weighted directed graph \(G = (V, E)\), with weight function \(w : E \rightarrow \mathbb{R}\), finds and outputs a negative-weight cycle in \(G\) if one such cycle exists. Also, analyze the complexity of \textsc{Find-Negative-Cycle}.

**Exercise 138.** Consider a text composed of \(n\) lines of up to 80 characters each. The text is stored in an array \(T\) where each line \(T[i]\) is an array of characters containing words separated by a single space.

\textbf{Question 1:} Write an algorithm \textsc{Sort-Lines-By-Word-Count}(\(T\)) that, with a worst-case complexity of \(O(n)\), sorts the lines in \(T\) in non-decreasing order of the number of words in the line. (\textbf{Hint:} lines have at most 80 characters, so the number of words in a line is also limited.)

\textbf{Question 2:} If you did not already do that for exercise 1, write an \textit{in-place} variant of the \textsc{Sort-Lines-By-Word-Count} algorithm. This algorithm, called \textsc{Sort-Lines-By-Word-Count-In-Place}, must also have a \(O(n)\) complexity to sort the set of lines, and may use only a constant amount of extra space to do that.

**Exercise 139.** Consider a weighted undirected graph \(G = (V, E)\) representing a group of programmers and their affinity for team work, such that the weight \(w(e)\) of an edge \(e = (u, v)\) is a number representing the ability of programmers \(u\) and \(v\) to work together on the same project. Write an algorithm \textsc{Best-Team-Of-Three} that outputs the best team of three programmers. The value of a team is considered to be the lowest affinity level between any two members of the team. So, the best team is the group of programmers for which the lowest affinity level between members of the group is maximal.

**Exercise 140.** Write an algorithm \textsc{Maximal-Non-Adjacent-Sequence-Weight}(\(A\)) that, given a sequence of numbers \(A = \langle a_1, a_2, ..., a_n \rangle\), computes, with worst-case complexity \(O(n)\), the maximal weight of any sub-sequence of non-adjacent elements in \(A\). A sub-sequence of non-adjacent elements may include \(a_i\) or \(a_{i+1}\) but not both, for all \(i\). For example, with \(A = \langle 2, 9, 6, 2, 6, 8, 5 \rangle\), \textsc{Maximal-Non-Adjacent-Sequence-Weight}(\(A\)) should return 20. (\textbf{Hint:} use a dynamic programming algorithm that scans the input sequence once.)

**Exercise 141.** Consider a trie rooted at node \(T\) that represents a set of character strings. For simplicity, assume that characters are from the Roman alphabet and that the letters of the alphabet are encoded with numeric values between 1 and 26. Write an algorithm \textsc{Print-Trie}(\(T\)) that prints all the strings stored in the trie.

**Exercise 142.** Write an algorithm \textsc{Print-In-Three-Columns}(\(A\)) that takes an array of words \(A\) and prints all the words in \(A\), in the given order left-to-right and top-to-bottom, such that the words are left-aligned in three columns. Words must be separated by at least one space horizontally, but in order to align words, the algorithm might have to print more spaces between words. For example, if \(A\) contains the words exam, algorithms, asymptotic, complexity, graph, greedy, lugano, np, quicksort, retake, september, then the output should be

\begin{verbatim}
exam algorithms asymptotic
complexity graph greedy
lugano np quicksort
retake september
\end{verbatim}

**Exercise 143.** Consider a binary search tree.

\textbf{Question 1:} Write an algorithm \textsc{BST-Median}(\(T\)) that takes the root \(T\) of a binary search tree and returns the median element contained in the tree. Also analyze the complexity of \textsc{BST-Median}(\(T\)). Can you do better?

\textbf{Question 2:} Assume now that the tree is balanced and also that each node \(t\) has an attribute \textit{t.weight} corresponding to the total number of nodes in the subtree rooted at \(t\) (including \(t\) itself). Write an algorithm \textsc{Better-BST-Median}(\(T\)) that improves on the complexity of \textsc{BST-Median}. Analyze the complexity of \textsc{Better-BST-Median}.
Exercise 144. Consider the following decision problem. Given a set of strings $S$, a number $w$, and a number $k$, output YES when there are at least $k$ strings in $S$ that share a common sub-string of length $w$, or NO otherwise. For example, if $S$ contains the strings exam, algorithms, asymptotic, complexity, graph, greedy, lugano, np, quicksort, retake, september, theory, practice, programming, math, art, truth, justice, with $w = 2$ and $k = 3$ the output should be YES, because the 3 strings graph, greedy, and programming share a common substring "gr" of length 2. The output should also be YES for $w = 3$ and $k = 3$ and for $w = 2$ and $k = 4$, but it should be NO for $w = 3$ and $k = 4$.

Question 1: Is this problem in NP? Write an algorithm that proves it is, or argue that it is not. (10')

Question 2: Is this problem in P? Write an algorithm that proves it is, or argue that it is not. (20')

Exercise 145. Consider the following sorting problem: you must reorder the elements of an array of numbers in-place so that odd numbers are in odd positions while even numbers are in even positions. If there are more even elements than odd ones in $A$ (or vice-versa) then those additional elements will be grouped at the end of the array. For example, with an initial sequence $A = \langle 50, 47, 92, 78, 76, 70, 36, 59, 30, 50, 43 \rangle$ the result could be this:

$A = \langle 47, 50, 7, 78, 59, 36, 43, 92, 60, 30, 50 \rangle$

Question 1: Write an algorithm called Alternate-Even-Odd $(A)$ that sorts $A$ in place as explained above. Also, analyze the complexity of Alternate-Even-Odd. (You might want to consider question 2 before you start solving this problem.) (20')

Question 2: If you have not done so already, write a variant of Alternate-Even-Odd that runs in $O(n)$ steps for an array $A$ of $n$ elements. (10')

Exercise 146. Write an algorithm called Four-Cycle $(G)$ that takes a directed graph represented with its adjacency matrix $G$, and that returns true if and only if $G$ contains a 4-cycle. A 4-cycle is a sequence of four distinct vertexes $a, b, c, d$ such that there is an arc from $a$ to $b$, from $b$ to $c$, from $c$ to $d$, and from $d$ to $a$. Also, analyze the complexity of Four-Cycle $(G)$. (20')

Exercise 147. Write an algorithm Find-Equal-Distance $(A)$ that takes an array $A$ of numbers, and returns four distinct elements $a, b, c, d$ of $A$ such that $a - b = c - d$, or nil if no such elements exist. Find-Equal-Distance must run in $O(n^2 \log n)$ time. (20')

Exercise 148. Consider the following algorithm that takes an array of numbers:

```
ALGO-X(A)
1    i = 1
2       while i < A.length
3          if A[i] > A[i + 1]
4              swap A[i] ↔ A[i + 1]
5          p = i
6          q = i + 1
7       for j = i + 2 to A.length
9                  p = j
11                 q = j
14    i = i + 2
```

Question 1: Explain what ALGO-X does and analyze its complexity. (5')

Question 2: Write an algorithm BETTER-ALGO-X that is functionally equivalent to ALGO-X but with a strictly better time complexity. (15')
Exercise 149. Consider the following definition of the height of a node \( t \) in a binary tree:

\[
\text{height}(t) = \begin{cases} 
0 & \text{if } t = \text{NIL} \\
1 + \max\{\text{height}(t.\text{left}), \text{height}(t.\text{right})\} & \text{otherwise.}
\end{cases}
\]

**Question 1:** Write an algorithm \( \text{HEIGHT}(t) \) that computes the height of a node \( t \). Also, analyze the complexity of your \( \text{HEIGHT} \) algorithm when \( t \) is the root of a tree of \( n \) nodes. (5')

**Question 2:** Consider now a binary search tree in which each node \( t \) has an attribute \( t.\text{height} \) that denotes the height of that node. Write a constant-time rotation algorithm \( \text{LEFT-ROTATE}(t) \) that performs a left rotation around node \( t \) and also updates the \( \text{height} \) attributes as needed. (5')

Exercise 150. Consider the following classic insertion algorithm for a binary search tree:

\[
\text{BST-INSERT}(t,k) =
\begin{array}{l}
\text{if } t = \text{NIL} \\
\text{return NEW-NODE}(k) \\
\text{else if } k \leq t.\text{key} \\
\quad t.\text{left} = \text{BST-INSERT}(t.\text{left},k) \\
\text{else} \\
\quad t.\text{right} = \text{BST-INSERT}(t.\text{right},k) \\
\text{return } t
\end{array}
\]

Write an algorithm \( \text{SORT-FOR-BALANCED-BST}(A) \) that takes an array of numbers \( A \), and prints the elements of \( A \) so that, if passed to \( \text{BST-INSERT} \), the resulting BST would be of minimal height. Also, analyze the complexity of your solution. (20')

Exercise 151. Consider the array of numbers:

\[A = \langle 69, 36, 68, 18, 36, 50, 9, 36, 36, 18, 8, 10 \rangle\]

**Question 1:** Does \( A \) satisfy the max-heap property? If not, fix it by swapping two elements. (5')

**Question 2:** Write an algorithm \( \text{MAX-HEAP-INSERT}(H,k) \) that inserts a key \( k \) in a max-heap \( H \). (10')

**Question 3:** Illustrate the behavior of \( \text{MAX-HEAP-INSERT} \) by applying it to array \( A \) (possibly corrected). In particular, write the content of the array after the insertion of each of the following keys, in this order: 69, 50, 60, 70. (5')

Exercise 152. Consider the following algorithm that takes an array of numbers:

\[
\text{ALGO-Y}(A) =
\begin{array}{l}
a = 0 \\
\text{for } i = 1 \text{ to } A.\text{length} - 1 \\
\quad \text{if } A[i] \text{ is even:} \\
\qquad x = x + 1 \\
\quad \text{else} \\
\qquad x = x - 1 \\
\text{if } x = 0 \text{ and } j - i > a \\
\quad a = j - i \\
\text{return } a
\end{array}
\]

**Question 1:** Explain what \( \text{ALGO-Y} \) does and analyze its complexity. (5')

**Question 2:** Write an algorithm \( \text{BETTER-ALGO-Y} \) that is functionally equivalent to \( \text{ALGO-Y} \) but with a strictly better time complexity. Also analyze the time complexity of \( \text{BETTER-ALGO-Y} \). (10')

**Question 3:** If you have not already done so for question 2, write a \( \text{BETTER-ALGO-Y} \) that is functionally equivalent to \( \text{ALGO-Y} \) but that runs in time \( O(n) \). (15')

Exercise 153. Write an algorithm \( \text{THREE-WAY-PARTITION}(A, v) \) that takes an array \( A \) of \( n \) numbers, and partitions \( A \) in-place in three parts, some of which might be empty, so that the left part \( A[1...p - 1] \) contains all the elements less than \( v \), the middle part \( A[p...q - 1] \) contains all the elements equal to \( v \), and the right part \( A[q...n] \) contains all the elements greater than \( v \). \( \text{THREE-WAY-PARTITION} \) must return the positions \( p \) and \( q \) and must run in time \( O(n) \). (20')
Exercise 154. A DNA strand is a sequence of nucleotides, and can be represented as a string over the alphabet $\Sigma = \{A, C, G, T\}$. Consider the problem of determining whether two DNA strands $s_1$ and $s_2$ are $k$-related in the sense that they share a sub-sequence of at least $k$ nucleotides.

Question 1: Is the problem in $NP$? Write an algorithm that proves it is, or argue that it is not. (10')

Question 2: Is the problem in $P$? Write an algorithm that proves it is, or argue that it is not. (20')

Exercise 155. Consider the following algorithm that takes an array of numbers:

\begin{algorithm}
\caption{ALGO-X(A)}
1. $y = -\infty$
2. $i = 1$
3. $j = 1$
4. $x = 0$
5. \textbf{while} $i \leq A.\text{length}$
6. \hspace{1em} $x = x + A[j]$
7. \hspace{1em} \textbf{if} $x > y$
8. \hspace{2em} $y = x$
9. \hspace{1em} \textbf{if} $j == A.\text{length}$
10. \hspace{2em} $i = i + 1$
11. \hspace{2em} $j = i$
12. \hspace{2em} $x = 0$
13. \hspace{1em} \textbf{else} $j = j + 1$
14. \textbf{return} $y$
\end{algorithm}

Question 1: Explain what ALGO-X does and analyze its complexity. (10')

Question 2: Write an algorithm BETTER-ALGO-X that is functionally equivalent to ALGO-X but with a strictly better time complexity. (20')

Exercise 156. Write an algorithm MAXIMAL-CONNECTED-SUBGRAPH($G$) that takes an undirected graph $G = (V, E)$ and prints the vertices of a maximal connected subgraph of $G$. (20')

Exercise 157. A system collects the positions of cars along a highway that connects two cities, A and B. The positions are grouped by direction in two arrays, $A$ and $B$. Thus $A$ contains the distances in kilometers from city A of the cars traveling towards city A. Write an algorithm CONGESTION($A$) that takes the array $A$ and prints a list of congested sections of the highway. A congested interval is a contiguous stretch of highway of 1km or more in which the density of cars is more than 50 cars per kilometer. CONGESTION($A$) must run in $O(n \log n)$ time. (20')

Exercise 158. The following matrix represents a directed graph over vertices $a, b, c, \ldots, \ell$. Rows and columns represent the source and destination of edges, respectively.

\begin{tabular}{cccccccccc}
    & a & b & c & d & e & f & g & h & i & j & k & \ell \\
a & & 1 & & & & & & & & & & \\
b & 1 & & 1 & & & & & & & & & \\
c & & 1 & & 1 & & & & & & & & \\
d & 1 & & 1 & & 1 & & & & & & & \\
e & & & 1 & & 1 & & & & & & & \\
f & & & & 1 & & 1 & & & & & & \\
g & & & & & & & & & & & & \\
h & & & & & & & & & & & & \\
i & & & & & & & & & & & & \\
j & & & & & & & & & & & & \\
k & & & & & & & & & & & & \\
l & & & & & & & & & & & & \\
\end{tabular}
Write the graph and the *DFS numbering* of the vertexes using the DFS algorithm. Every iteration through vertexes or adjacent edges is performed in alphabetic order. (*Hint:* the DFS numbering of a vertex $v$ is a pair of numbers representing the "time" at which DFS discovers $v$ and the time DFS leaves $v$.)

**Exercise 159.** Consider an array $A$ of $n$ numbers that is initially sorted, in ascending order, and then modified so that $k$ of its elements are decreased in value.

*Question 1:* Write an algorithm that sorts $A$ in-place in time $O(kn)$.

*Question 2:* Write an algorithm that sorts $A$ in time $O(n + k \log k)$ but not necessarily in-place.

**Exercise 160.** Consider the decision version of the well-known vertex cover problem: given a graph $G = (V, E)$ and an integer $k$, output 1 if $G$ contains a vertex cover of size $k$. A vertex cover is a set of vertexes $S \subseteq V$ such that, for each edge $(u, v) \in E$, either vertex $u$ is in $S$ or vertex $v$ is in $S$. Write an algorithm that proves that vertex cover is in $\text{NP}$. (20')

**Exercise 161.** Write an algorithm that transforms a min-heap $H$ into a max-heap in-place.

(10')

**Exercise 162.** We say that two words $x$ and $y$ are linked to each other if they differ by a single letter, or more specifically by one edit operation, meaning an insertion, a deletion, or a change in a single character. For example, "fun" and "pun" are linked, as are "flower" and "lower", "port" and "post", "canton" and "cannon", and "cat" and "cast".

*Question 1:* Write an algorithm $\text{LINKED}(x, y)$ that takes two words $x$ and $y$ and, in linear time, returns $\text{true}$ if $x$ and $y$ are linked to each other, or false otherwise.

*Question 2:* Write an algorithm $\text{WORD-CHAIN}(W, x, y)$ that takes an array of words $W$ and two words $x$ and $y$, and outputs a minimal sequence of words $x, w_1, w_2, \ldots, y$ that starts with $x$ and ends with $y$ where $w_1, w_2, \ldots$ are all words from $W$, and each word in the sequence is linked to the words adjacent to it. For example, if $W$ is a dictionary of English words, and $x$ and $y$ are "first" and "last", respectively, then the output might be: first fist list last.

(30')

**Exercise 163.** Write an algorithm $\text{MAX-HEAP-INSERT}(H, k)$ that inserts a new value $k$ in a max-heap $H$. Briefly analyze the complexity of your solution.

(10')

**Exercise 164.** Consider an algorithm $\text{FIND-ELEMENTS-AT-DISTANCE}(A, k)$ that takes an array $A$ of $n$ integers sorted in non-decreasing order and returns true if and only if $A$ contains two elements $a_i$ and $a_j$ such that $a_i - a_j = k$.

*Question 1:* Write a version of the $\text{FIND-ELEMENTS-AT-DISTANCE}$ algorithm that runs in $O(n \log n)$ time. Briefly analyze the complexity of your solution.

*Question 2:* Write a version of the $\text{FIND-ELEMENTS-AT-DISTANCE}$ algorithm that runs in $O(n)$ time. Briefly analyze the complexity of your solution.

(20')

**Exercise 165.** Write an algorithm $\text{PARTITION-PRIMES-COMPOSITES}(A)$ that takes an array $A$ of $n$ integers such that $1 < A[i] \leq m$ for all $i$, and partitions $A$ in-place so that all primes precede all composites in $A$. Analyze the complexity of your solution as a function of $n$ and $m$. Reminder: an integer greater than 1 is prime if it is divisible by only two positive integers (itself and 1) or otherwise it is composite.

(20')

**Exercise 166.** Consider the following classic insertion algorithm for a binary search tree:

1. if $t = \text{NIL}$
2. return $\text{NEW-NODE}(k)$
3. else if $k \leq t.\text{key}$
4. $t.\text{left} = \text{BST-INSERT}(t.\text{left}, k)$
5. else $t.\text{right} = \text{BST-INSERT}(t.\text{right}, k)$
6. return $t$

Write an algorithm $\text{SORT-FOR-BALANCED-BST}(A)$ that takes an array of numbers $A$, and prints the elements of $A$ in a new order so that, if the printed sequence is passed to $\text{BST-INSERT}$, the resulting BST would be of minimal height. Also, analyze the complexity of your solution.

(20')
Exercise 167. Consider a game in which, given a multiset of positive numbers $A$ (possibly with repeated values) a player can simplify $A$ by removing, one at a time, an element $a_k$ if there are two other elements $a_i, a_j$ such that $a_i + a_j = a_k$.

**Question 1:** Write an algorithm called MINIMAL-SIMPLIFIED-SUBSET($A$) that, given a multiset $A$ of $n$ numbers, returns a minimal simplified subset $X \subseteq A$. The result $X$ is minimal in the sense that no smaller set can be obtained with a sequence of simplifications starting from $A$. For example, with $A = \{7, 89, 11, 88, 106, 4, 28, 71, 17\}$, a valid result would be $X = \{7, 89, 4, 71, 17\}$. Briefly analyze the complexity of your solution.

**Question 2:** Write a MINIMAL-SIMPLIFIED-SUBSET($A$) algorithm that runs in $O(n^2)$. If you have already done so for exercise 1, then simply say so.

Exercise 168. Consider the following algorithm that takes an integer $n$ as input:

```
ALGORITHM-X(n)
1  c = 0
2  a = n
3  while $a > 1$
4    b = 1
5      while $b \leq a^2$
6        c = c + 1
7        b = 2b
8      a = a/2
9  return c
```

Write the complexity of ALGORITHM-X as a function of $n$. Justify your answer.

Exercise 169. Write an algorithm FIND-CYCLE($G$) that, given a directed graph $G$, returns TRUE if and only if $G$ contains a cycle. You may assume the representation of your choice for $G$.

Exercise 170. A breadth-first search over a graph $G$ returns a vector $\pi$ that represents the resulting breadth-first tree, where the parent $\pi[v]$ of a vertex $v$ is the next-hop from $v$ on the tree towards the source of the breadth-first search.

**Question 1:** Write an algorithm BFS-FIRST-COMMON-ANCESTOR($\pi, u, v$) that finds the first common ancestor of two given nodes in the breadth-first tree, or NULL if $u$ and $v$ are not connected in $G$. The complexity of BFS-FIRST-COMMON-ANCESTOR must be $O(n)$. Briefly analyze the space complexity of your solution.

**Question 2:** Write an algorithm BFS-FIRST-COMMON-ANCESTOR-$2(\pi, D, u, v)$ that is also given the distance vector $D$ resulting from the same breadth first search. BFS-FIRST-COMMON-ANCESTOR-$2$ must be functionally equivalent to BFS-FIRST-COMMON-ANCESTOR (as defined in Exercise 1) but with space complexity $O(1)$.

Exercise 171. Consider the height and the black height of a red-black tree.

**Question 1:** What are the minimum and maximum heights of a red-black tree containing 10 keys? Exemplify your answers by drawing a minimal and a maximal tree. Clearly identify each node as red or black.

**Question 2:** What are the minimum and maximum black heights of a red-black tree containing 10 keys? Exemplify your answers by drawing a minimal and a maximal tree. Clearly identify each node as red or black.

Exercise 172. Consider an algorithm BST-FIND-SUM($T, v$) that, given a binary search tree $T$ containing $n$ distinct numeric keys, and given a target value $v$, finds and returns two nodes in $T$ whose keys add up to $v$. The algorithm returns NULL if no such keys exist in $T$. BST-FIND-SUM may not modify the tree, and may only use a constant amount of memory.

**Question 1:** Write BST-FIND-SUM. You may use the basic algorithms that operate on binary search trees (BST-MIN, BST-SUCCESSOR, BST-SEARCH, etc.) without defining them explicitly.

**Question 2:** Write a variant of BST-FIND-SUM($T, v$) that works in $O(n)$ time. If your solution to Exercise 1 already has this complexity bound, then simply say so.
Exercise 173. Consider this decision problem: given a set of integers \(X = \{x_1, x_2, \ldots, x_n\}\), and an integer \(k\), return 1 if there are \(k\) elements in \(X\) that are pairwise relatively prime, or return 0 otherwise. Two integers are relatively prime if their only common divisor is 1. For example, for \(X = \{5, 6, 10, 14, 18, 21, 49\}\) and \(k = 3\), the result is 1, since the 3 elements 5, 18, 49 are pairwise relatively prime (5 and 18 have no common divisor other than 1, and the same is true for 5 and 49, and 18 and 49). However, for the same set \(X = \{5, 6, 10, 14, 18, 21, 49\}\) and \(k = 4\), the solution is 0, since no four elements from \(X\) are all pairwise relatively prime.

Question 1: Is this problem in NP? Write an algorithm that proves it is, or argue that it is not. (20')

Question 2: (BONUS) Is this problem NP-hard? Prove it. (60')

Exercise 174. You are given a square matrix \(M \in \mathbb{R}^{n \times n}\) whose elements are sorted both row-wise and column-wise. In other words, rows and columns are non-decreasing sequences. Formally, for every element \(m_{i,j} \in M\), \((j < n \Rightarrow m_{i,j} \leq m_{i,j+1}) \land (i < n \Rightarrow m_{i,j} \leq m_{i+1,j})\). Write an algorithm \(\text{Search-In-Sorted-Matrix}(M, x)\) that returns \(true\) if \(x \in M\) or \(false\) otherwise. The time complexity of \(\text{Search-In-Sorted-Matrix}\) must be \(O(n \log n)\). Justify that your solution has such a complexity. (20')

Exercise 175. Consider the following algorithm that takes an array \(A\) of positive integers:

\[
\begin{align*}
\text{ALGO-X}(A) & \quad 1 \quad B = \text{copy of } A \\
& \quad 2 \quad i = 1 \\
& \quad 3 \quad x = 1 \\
& \quad 4 \quad \textbf{while } i \leq \text{A.length} \quad \\
& \quad 5 \quad B[i] = B[i] - 1 \\
& \quad 6 \quad \textbf{if } B[i] == 0 \\
& \quad 7 \quad \quad B[i] = A[i] \\
& \quad 8 \quad \quad i = i + 1 \\
& \quad 9 \quad \textbf{else } x = x + 1 \\
& \quad 10 \quad i = 1 \\
& \quad \textbf{return} x 
\end{align*}
\]

Question 1: Briefly explain what \(\text{ALGO-X}\) does and analyze the complexity of \(\text{ALGO-X}\). (10')

Question 2: Write an algorithm called \(\text{BETTER-ALGO-X}\) that is functionally identical to \(\text{ALGO-X}\) but with a strictly better complexity. Analyze the complexity of \(\text{BETTER-ALGO-X}\). (10')

Exercise 176. Consider the following algorithm that takes an array \(A\) of numbers:

\[
\begin{align*}
\text{ALGO-Y}(A) & \quad 1 \quad i = 2 \\
& \quad 2 \quad j = 1 \\
& \quad 3 \quad x = -\infty \\
& \quad 4 \quad \textbf{while } i \leq \text{A.length} \quad \\
& \quad 5 \quad \textbf{if } |A[i] - A[j]| > x \\
& \quad 6 \quad \quad x = |A[i] - A[j]| \\
& \quad 7 \quad \quad j = j + 1 \\
& \quad 8 \quad \textbf{if } j == i \\
& \quad 9 \quad \quad i = i + 1 \\
& \quad 10 \quad \quad j = 1 \\
& \quad 11 \quad \textbf{return} x 
\end{align*}
\]

Question 1: Briefly explain what \(\text{ALGO-Y}\) does and analyze the complexity of \(\text{ALGO-Y}\). (10')

Question 2: Write an algorithm called \(\text{BETTER-ALGO-Y}\) that is functionally identical to \(\text{ALGO-Y}\) but with a complexity \(O(n)\). (10')

Exercise 177. Write an algorithm \(\text{BTREE-LOWER-BOUND}(T, k)\) that, given a B-tree \(T\) and a value \(k\), returns the least key \(v\) in \(T\) such that \(k \leq v\), or \(\text{NULL}\) if no such key exist. Also, analyze the complexity of \(\text{BTREE-LOWER-BOUND}\). (Reminder: a node \(x\) in a B-tree has the following properties:
\(x.n\) is the number of keys, \(X.\text{key}[1] \leq x.\text{key}[2] \leq \ldots x.\text{key}[x.n]\) are the keys, \(x.\text{leaf}\) tells whether \(x\) is a leaf, and \(x.\text{c}[1], x.\text{c}[2], \ldots, x.\text{c}[x.n + 1]\) are the pointers to \(x\)’s children.

**Exercise 178.** Write an algorithm BST-LEAST-DIFFERENCE\((T)\) that, given a binary search tree \(T\) containing numeric keys, returns in \(O(n)\) time the minimal distance between any two keys in the tree.

**Exercise 179.** A connected component of an undirected graph \(G\) is a maximal set of vertices that are connected to each other (directly or indirectly). Thus the vertices of a graph can be partitioned into connected components. Write an algorithm CONNECTED-COMPONENTS\((G)\) that, given an undirected graph \(G\), returns the number of connected components in \(G\). Also, analyze the complexity of CONNECTED-COMPONENTS.

**Exercise 180.** Rank the following functions in decreasing order of growth by indicating their rank next to the function, as in the first line (\(n^n\) is the fastest growing function). If any two functions \(f_i\) and \(f_j\) are such that \(f_i = \Theta(f_j)\), then rank them at the same level.

<table>
<thead>
<tr>
<th>function</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>(f_0(n) = n^n)</td>
<td>1</td>
</tr>
<tr>
<td>(f_1(n) = \log^2(n))</td>
<td></td>
</tr>
<tr>
<td>(f_2(n) = n!)</td>
<td></td>
</tr>
<tr>
<td>(f_3(n) = \log(n^2))</td>
<td></td>
</tr>
<tr>
<td>(f_4(n) = n)</td>
<td></td>
</tr>
<tr>
<td>(f_5(n) = \log(n!)</td>
<td></td>
</tr>
<tr>
<td>(f_6(n) = \log \log n)</td>
<td></td>
</tr>
<tr>
<td>(f_7(n) = n \log n)</td>
<td></td>
</tr>
<tr>
<td>(f_8(n) = \sqrt{n^2})</td>
<td></td>
</tr>
<tr>
<td>(f_9(n) = 2^n)</td>
<td></td>
</tr>
</tbody>
</table>

**Hint:** as a reminder, consider the following mathematical definitions and facts: (definition of factorial) \(n! = 1 \cdot 2 \cdot 3 \cdot \ldots (n - 1) \cdot n\); (facts about the logarithm) \(\log(ab) = \log a + \log b\), and therefore \(\log(a^k) = k \log a\).

**Exercise 181.** Write an algorithm called MINIMAL-COVERING-SQUARE\((P)\) that takes a sequence \(P\) of \(n\) points in the 2D Euclidean plane, each defined by its Cartesian coordinates \(P[i].x\) and \(P[i].y\), and returns the area of a minimal axis-aligned square that covers all points in \(P\). An axis-aligned square is one in which the sides are parallel to X and Y axes. MINIMAL-COVERING-SQUARE must run in time \(O(n)\).

**Exercise 182.** A sequence of numbers is called unimodal if it is first strictly increasing and then strictly decreasing. For example, the sequence 1, 5, 19, 17, 12, 8, 5, 3, 2 is unimodal, while the sequence 1, 5, 3, 7, 4, 2 is not. Write an algorithm UNIMODAL-FIND-MAXIMUM\((A)\) that finds the maximum of a unimodal sequence \(A\) of \(n\) numbers in time \(O(\log n)\).

**Exercise 183.** Consider the following algorithm ALGO-X\((A,k)\) that takes an array \(A\) of \(n\) objects and an integer \(k\):
Exercise 186. Big Brother tracks a set of cell-phone users by recording every cell antenna the user connects to. In particular, for each user $u_i$, Big Brother stores a time-ordered sequence $S_i = (t_1, a_1), (t_2, a_2), \ldots$ that records that user $u_i$ was connected to antenna $a_1$ starting at time $t_1$, and later switched to antenna $a_2$ at time $t_2 > t_1$, and so on. Write an algorithm called \textsc{Group-Of-K}(S_1, S_2, \ldots, S_m, k) that finds whether there is a time $t^*$ when a group of at least $k$ users are connected to the same antenna. In this case, \textsc{Group-Of-K} must output the time $t^*$ and the antenna $a^*$. Otherwise, \textsc{Group-Of-K} must output \textsc{NULL}. \textsc{Group-Of-K} must run in time $O(n \log m)$ where $n$ is the total number of entries in all the sequences, so $n = |S_1| + |S_2| + \cdots + |S_m|$. You may use common data structures and algorithms without specifying those algorithms completely.

Exercise 187. Consider the following algorithm that takes an array $A$ of integers:

```c
Exercise 184.
\textsc{Three-Way-Partition}(A, begin, end) chooses a pivot element from the sub-array $A[\text{begin} \ldots \text{end} - 1]$, and partitions the sub-array in-place into three parts (two of which might be empty): $A[\text{begin} \ldots q_1 - 1]$ containing all the elements less than the pivot, $A[q_1 \ldots q_2 - 1]$ containing all the elements equal to the pivot, and $A[q_2 \ldots \text{end} - 1]$ containing all elements greater than the pivot.

Question 1: Write a \textsc{Three-Way-Partition}(A, begin, end) algorithm that runs in time $O(n)$, where $n = \text{end} - \text{begin}$, and that returns the partition boundaries $q_1, q_2$. You may assume that $\text{begin} < \text{end}$.

Question 2: Use the \textsc{Three-Way-Partition} algorithm to write a better variant of the classic quick-sort algorithm. Also, describe in which cases this variant would perform significantly better than the classic algorithm.

Exercise 185. The following algorithm \textsc{Sum}(A, s) takes an array $A$ of $n$ numbers and a number $s$. Describe what \textsc{Sum}(A, s) does at a high level and analyze its complexity in the best and worst cases. Justify your answer by clearly describing the best- and worst-case input, as well as the behavior of the algorithm in each case.

```c
Exercise 186.

\begin{verbatim}
ALGO-X(A, k)
1  l = −∞
2  r = +∞
3  for i = 1 to A.length − k
4       for j = i + 1 to A.length
5          if \textsc{ALGO-Y}(A, i, j) ≥ k
6            if r − l > j − i
7                l = i
8                r = j
9    return l, r

\textsc{ALGO-Y}(A, a, b)
1  m = 1
2  for i = a to b
3  c = 1
5    c = c + 1
6  return m

Question 1: Explain what \textsc{ALGO-X}(A, k) does and analyze its complexity. Do not simply paraphrase the code. Instead, explain the high level semantics, independent of the code.

Question 2: Write an algorithm \textsc{Better-ALGO-X}(A, k) with exactly the same functionality as \textsc{ALGO-X}(A, k), but with a strictly better complexity. Also, analyze the complexity of \textsc{Better-ALGO-X}(A, k).
\end{verbatim}

Exercise 187. Consider the following algorithm that takes an array $A$ of integers:

```c
ALGO-X(A, k)
1  l = −∞
2  r = +∞
3  for i = 1 to A.length − k
4       for j = i + 1 to A.length
5          if \textsc{ALGO-Y}(A, i, j) ≥ k
6            if r − l > j − i
7                l = i
8                r = j
9    return l, r

\textsc{ALGO-Y}(A, a, b)
1  m = 1
2  for i = a to b
3  c = 1
5    c = c + 1
6  return m

Question 1: Write an algorithm \textsc{Better-ALGO-X}(A, k) with exactly the same functionality as \textsc{ALGO-X}(A, k), but with a strictly better complexity. Also, analyze the complexity of \textsc{Better-ALGO-X}(A, k).

Question 2: Write a \textsc{Better-ALGO-X}(A, k) with exactly the same functionality as \textsc{Better-ALGO-X}(A, k), but with a strictly better complexity. Also, analyze the complexity of \textsc{Better-ALGO-X}(A, k).

Question 1:

```c
Exercise 185.
\textsc{Sum}(A, s)
1  return \textsc{Sum-R}(A, s, 1, A.length)

\textsc{Sum-R}(A, s, b, e)
1  if b > e and s == 0
2    return TRUE
3  else if b ≤ e and \textsc{Sum-R}(A, s, b + 1, e)
4    return TRUE
5  else if b ≤ e and \textsc{Sum-R}(A, s − A[b], b + 1, e)
6    return TRUE
7  else return FALSE

Question 2:

Exercise 186. Big Brother tracks a set of $m$ cell-phone users by recording every cell antenna the user connects to. In particular, for each user $u_i$, Big Brother stores a time-ordered sequence $S_i = (t_1, a_1), (t_2, a_2), \ldots$ that records that user $u_i$ was connected to antenna $a_1$ starting at time $t_1$, and later switched to antenna $a_2$ at time $t_2 > t_1$, and so on. Write an algorithm called \textsc{Group-Of-K}(S_1, S_2, \ldots, S_m, k) that finds whether there is a time $t^*$ when a group of at least $k$ users are connected to the same antenna. In this case, \textsc{Group-Of-K} must output the time $t^*$ and the antenna $a^*$. Otherwise, \textsc{Group-Of-K} must output \textsc{NULL}. \textsc{Group-Of-K} must run in time $O(n \log m)$ where $n$ is the total number of entries in all the sequences, so $n = |S_1| + |S_2| + \cdots + |S_m|$. You may use common data structures and algorithms without specifying those algorithms completely.

Exercise 186. Big Brother tracks a set of cell-phone users by recording every cell antenna the user connects to. In particular, for each user $u_i$, Big Brother stores a time-ordered sequence $S_i = (t_1, a_1), (t_2, a_2), \ldots$ that records that user $u_i$ was connected to antenna $a_1$ starting at time $t_1$, and later switched to antenna $a_2$ at time $t_2 > t_1$, and so on. Write an algorithm called \textsc{Group-Of-K}(S_1, S_2, \ldots, S_m, k) that finds whether there is a time $t^*$ when a group of at least $k$ users are connected to the same antenna. In this case, \textsc{Group-Of-K} must output the time $t^*$ and the antenna $a^*$. Otherwise, \textsc{Group-Of-K} must output \textsc{NULL}. \textsc{Group-Of-K} must run in time $O(n \log m)$ where $n$ is the total number of entries in all the sequences, so $n = |S_1| + |S_2| + \cdots + |S_m|$. You may use common data structures and algorithms without specifying those algorithms completely.

Exercise 187. Consider the following algorithm that takes an array $A$ of integers:

```c
Exercise 185.
\textsc{Sum}(A, s)
1  return \textsc{Sum-R}(A, s, 1, A.length)

\textsc{Sum-R}(A, s, b, e)
1  if b > e and s == 0
2    return TRUE
3  else if b ≤ e and \textsc{Sum-R}(A, s, b + 1, e)
4    return TRUE
5  else if b ≤ e and \textsc{Sum-R}(A, s − A[b], b + 1, e)
6    return TRUE
7  else return FALSE

Question 2:

Exercise 186. Big Brother tracks a set of $m$ cell-phone users by recording every cell antenna the user connects to. In particular, for each user $u_i$, Big Brother stores a time-ordered sequence $S_i = (t_1, a_1), (t_2, a_2), \ldots$ that records that user $u_i$ was connected to antenna $a_1$ starting at time $t_1$, and later switched to antenna $a_2$ at time $t_2 > t_1$, and so on. Write an algorithm called \textsc{Group-Of-K}(S_1, S_2, \ldots, S_m, k) that finds whether there is a time $t^*$ when a group of at least $k$ users are connected to the same antenna. In this case, \textsc{Group-Of-K} must output the time $t^*$ and the antenna $a^*$. Otherwise, \textsc{Group-Of-K} must output \textsc{NULL}. \textsc{Group-Of-K} must run in time $O(n \log m)$ where $n$ is the total number of entries in all the sequences, so $n = |S_1| + |S_2| + \cdots + |S_m|$. You may use common data structures and algorithms without specifying those algorithms completely.

Exercise 187. Consider the following algorithm that takes an array $A$ of integers:
is defined by two coordinates at the same elevation. Analyze the complexity of your solutions showing a worst-case input.

An undirected graph \( G \) is bipartite when its vertices can be partitioned into two sets \( V_A, V_B \) such that each edge in \( G \) connects a vertex in \( V_A \) with a vertex in \( V_B \). In other words,
no two vertices in $V_A$ are adjacent, and no two vertices in $V_B$ are adjacent. To exemplify, see the
graphs below.

Write an algorithm $\text{Is-Bipartite}(G)$ that takes an undirected graph $G$ and outputs
true if and only if $G$ is bipartite. (Hint: you may use a simple BFS in which you keep track of which vertex is in
which partition.)

Exercise 195. Algorithm $\text{Is-Good}(x)$ classifies a number $x$ as “good” or “not good” in constant
time $O(1)$.

Question 1: Write an algorithm $\text{Good-Are-Adjacent}(A)$ that takes a sequence of numbers and,
using algorithm $\text{Is-Good}(\cdot)$, returns true if all the “good” numbers in $A$ are adjacent, or
false otherwise. $\text{Good-Are-Adjacent}(A)$ must not change the input sequence $A$ in any way, may allocate
only a constant amount of memory, and must run in time $O(n)$.

Exercise 196. Consider the following decision problem: given a sequence of numbers $A$ and an
integer $k$, returns true if $A$ contains at least $k$ identical values, or false otherwise. Is the problem
in NP? Write an algorithm that proves it is, or argue the opposite. Is the problem in P? Write an
algorithm that proves it is, or argue the opposite.

Exercise 197. Write an algorithm $\text{Maximal-Common-Substring}(X,Y)$ that takes two strings $X$
and $Y$, and returns the maximal length of a common substring of $X$ and $Y$. For example, if $X =$
‘BDDBADCDCCDCBAD’ and $Y = ‘DDCBCDAABAAC’, the output should be 3, since there is a 3-
character common substring (‘DCB’) but no 4-character common substring. Analyze the complexity
of your solution.

Exercise 198. We say that a node in a binary tree is unbalanced when the number of nodes in
its left subtree is more than twice the number of nodes in its right subtree plus one, or vice-
versa. Write an algorithm $\text{BST-Count-Unbalanced-Nodes}(t)$ that takes a binary search tree $t$
(the root), and returns the number of unbalanced nodes in the tree. Analyze the complexity
of $\text{BST-Count-Unbalanced-Nodes}(t)$. (Hint: an algorithm can return multiple values. For example,
the statement $\text{return } x, y$ returns a pair of values, and if $f()$ returns a pair of values, you can read
them with $a, b = f()$.)

Exercise 199. Consider the following algorithm that takes an array $A$ of numbers:

$$
\begin{align*}
\text{ALGO-X}(A) & \\
1 & x = 0 \\
2 & \text{for } i = 1 \text{ to } A.\text{length} - 1 \\
3 & \quad \text{for } j = i + 1 \text{ to } A.\text{length} \\
4 & \quad \quad \text{if } \text{ALGO-Y}(A, i, j) \text{ and } A[j] - A[i] > x \\
5 & \quad \quad x = A[j] - A[i] \\
6 & \text{return } x
\end{align*}
$$

Question 1: Briefly explain what $\text{ALGO-X}$ does and analyze the complexity of $\text{ALGO-X}$ by describing
a worst-case input.

Question 2: Write an algorithm $\text{LINEAR-ALGO-X}(A)$ that is equivalent to $\text{ALGO-X}$ but runs in linear
time.
**Exercise 200.** Let $P$ be an array of points on a plane, each with its Cartesian coordinates $P[i].x$ and $P[i].y$.

*Question 1:* Write an algorithm \textsc{Find-Square}(P) that returns \texttt{true} if and only if there are four points in $P$ that form a square. Briefly analyze the complexity of your solution. (10')

*Question 2:* Write an algorithm \textsc{Find-Square}(P) that solves the problem of Exercise 1 in time $O(n^2 \log n)$. If your solution for Exercise 1 already does that, then simply say so. (20')

**Exercise 201.** Implement a priority queue based on a heap. You must implement the following algorithms:

- \textsc{Initialize}(Q) creates an empty queue. The complexity of \textsc{Initialize} must be $O(1)$.
- \textsc{Enqueue}(Q, obj, p) adds an object obj with priority p to a queue Q. The complexity of \textsc{Enqueue} must be $O(\log n)$.
- \textsc{Dequeue}(Q) extracts and returns an object from a queue Q. The returned object must be among the objects in the queue that were inserted with the lowest priority. The complexity of \textsc{Dequeue} must be $O(\log n)$. (20')

**Exercise 202.** Implement an algorithm \textsc{Maximal-Distance}(A) that takes an array $A$ of numbers and returns the maximal distance between any two distinct elements in $A$, or 0 if $A$ contains less than two elements. \textsc{Maximal-Distance}(A) must run in time $O(n)$. (10')

**Exercise 203.** The height of a binary tree is the maximal number of nodes on a branch from the root to a leaf node. In other words, it is the maximal number of nodes traversed by a simple path starting at the root. Implement an algorithm \textsc{BST-Height}(t) that returns the height of a binary search tree rooted at node $t$. \textsc{BST-Height}(t) must run in time $O(n)$. (10')

**Exercise 204.** Consider the following decision problem: given a graph $G = (V,E)$ where the edges are weighted by a weight function $w : E \to \mathbb{R}$, and given a number $t$, output \texttt{true} if there is a set of non-adjacent edges $S = \{e_1,e_2,\ldots,e_k\}$ of total weight greater or equal to $t$, so $\sum w(e_i) \geq t$; or output \texttt{false} otherwise. For example, the vertices could represent people, say the students in the Algorithms class, and an edge $e = (u,v)$ with weight $w(e)$ could represent the affinity of the couple $(u,v)$. The question is then, given an affinity value $t$, tell whether the students in the Algorithms class can form monogamous couples of total affinity value at least $t$. Argue whether this decision problem is in \texttt{NP} or not, and if it is, then write an algorithm that proves it. (20')

**Exercise 205.** Consider the following game: you are given a set of $n$ valuable objects placed on a 2D plane with non-negative $x, y$ coordinates. In practice, you are given three arrays $X, Y, V$, such that $X[i], Y[i], \text{ and } V[i]$ are the $x$ and $y$ coordinates and the value of object $i$, respectively. You start from position 0, 0, and can only move horizontally to the right (increasing your $x$ coordinate) or vertically upward (increasing your $y$ coordinate). Your goal is to reach and collect valuable objects. Write an algorithm \textsc{Maximal-Game-Value}(X, Y, V) that returns the maximal total value you can achieve in a given game. (30')

**Exercise 206.** Write an algorithm \textsc{Maximal-Substring}(S) that takes an array $S$ of strings, and returns a string $x$ of maximal length such that $x$ is a substring of every string $S[i]$. Also, analyze the complexity of \textsc{Maximal-Substring} as a function of the size $n = |S|$ of the input array, and the maximal size $m$ of any string in $S$. (20')

**Exercise 207.** Consider the following algorithm that takes an array $A$ of numbers:
Exercise 208. Write an algorithm \textsc{Graph-Degree}(G) that takes an undirected graph represented by its adjacency matrix \( G \) and computes the degree of \( G \). The degree of a graph is the maximal degree of any vertex of \( G \). The degree of a vertex \( v \) is the number of edges that are adjacent to \( v \). Also analyze the complexity of \textsc{Graph-Degree}(G).

Exercise 209. Write an algorithm \textsc{Find-3-Cycle}(G) that takes an undirected graph represented as an adjacency list, and returns \textsc{true} if \( G \) contains a cycle of length 3, or \textsc{false} otherwise. Also, analyze the complexity of \textsc{Find-3-Cycle}(G).

Exercise 210. Write an algorithm \textsc{Longest-Common-Prefix}(S) that takes an array of strings \( S \), and returns the maximal length of a string that is a prefix of at least two strings in \( S \). Also, analyze the complexity of your solution as a function of the size \( n \) of the input array \( S \), and the maximal size \( m \) of any string in \( S \). For example, with \( S = [ "ciao", "lugano", "bella" ] \) the result is 0, because the only common prefix is the empty string, while with \( S = [ "professor", "prefers", "to", "teach", "programming" ] \) the result is 3 because "pro" is a prefix of at least two strings.

Exercise 211. Write an algorithm \textsc{Longest-K-Common-Prefix}(S, k) that takes an array of strings \( S \) and an integer \( k \), and returns the maximal length of a string that is a prefix of at least \( k \) strings in \( S \). Also, analyze the complexity of your solution as a function of \( k \), the size \( n \) of the input array \( S \), and the maximal size \( m \) of any string in \( S \). For example, with \( S = [ "algorithms", "and", "data", "structures" ] \) and \( k = 3 \), the result is 0, because the only common prefix common to at least three strings is the empty string. While with \( S = [ "professor", "prefers", "to", "teach", "programming" ] \) and \( k = 3 \), the result is 2 because the longest prefix common to at least three strings is "pr".

Exercise 212. Consider the following decision problem: given a directed and weighted graph \( G \) (with weighted arcs), output \textsc{true} if and only if \( G \) contains a path of length 3 and of negative total weight; otherwise output \textsc{false}. Is the problem in \( \text{NP} \)? Write an algorithm that proves it is, or argue the opposite. Is the problem in \( \text{P} \)? Write an algorithm that proves it is, or argue the opposite.

Exercise 213. Given a collection \( A \) of numbers and a number \( x \), the upper bound of \( x \) in \( A \) is the minimal value \( a \in A \) such that \( x \leq a \), or \text{null} if no such value exists. For example, given \( A = [ 7, 20, 1, 3, 4, 3, 31, 50, 9, 11 ] \), the upper bound of \( x = 15 \) is 20, while the upper bound of \( x = 9 \) is 9 and the upper bound of \( x = 51 \) is \text{null}.

Question 1: Write an algorithm \textsc{Upper-Bound}(A, x) that returns the upper bound of \( x \) in an array \( A \). Also analyze the complexity of \textsc{Upper-Bound}.

Question 2: Write an algorithm \textsc{Upper-Bound-Sorted}(A, x) that returns the upper bound of \( x \) in a sorted array \( A \) in time \( o(n) \). Analyze the complexity of \textsc{Upper-Bound-Sorted}.

Question 3: Write an algorithm \textsc{Upper-Bound-BST}(T, x) that returns the upper bound of \( x \) in a binary search tree \( T \). Analyze the complexity of \textsc{Upper-Bound-BST}.
Solutions

WARNING: solutions are very sparse, meaning that many are missing, most of the solutions are only sketched at a high level, and many may be incorrect! Please, consider contributing your solutions, including alternative solutions, and please report any error you might find to the author (Antonio Carzaniga <antonio.carzaniga@usi.ch>.

▷ Solution 57
Quick-sort. Best-case is $O(n \log n)$, worst-case is $O(n^2)$.

▷ Solution 58
Algorithm-I sorts the input array in-place. In the best case, the algorithm terminates in the first execution of the outer loop, with the condition $s = $ TRUE. This is the case when the inner loop does not swap a single element of the array, meaning that the array is already sorted. So, the best-case complexity is $O(n)$. Conversely, the worst case is when each iteration of the outer loop swaps at least one element. This happens when the array is sorted in reverse order. So, the worst-case complexity is $O(n^2)$.

Algorithm-II sorts the input array in-place so that the value $v = A[0]$, that is the element originally at position 0, ends up in position $q$, and every other element less than $v$ ends up somewhere in $A[1 \ldots q - 1]$, that is to the left of $q$, and every other element less than or equal to $v$ ends up somewhere in $A[q + 1 \ldots |A|]$. In other words, Algorithm-II partitions the input array in-place using the first element as the “pivot”. The loop closes the gap between $i$ and $j$, which are initially the first and last position in the array, respectively. Each iteration either moves $i$ to the right or $j$ to the left, so each iteration reduces the gap by one. Therefore, in any case—worst case is the same as the best case—the complexity is $O(n)$.

Solution 79
First figure out the frequencies and sort the characters by frequency. Then we proceed with the
derivation:

Solution 81

\[ \text{IsColorValid}(G = (V,E), v) \]

1 for each \( u \) adjacent to \( v \)
2 if \( \text{color}[u] = \text{color}[v] \)
3 return FALSE
4 return TRUE
COLOR($G = (V, E)$)
1 for each $v \in V$
2 $color[v] = 0$
3 for each $v \in V$
4 $color[v] = 1$
5 while IsColorValid($G = (V, E), v$) = false
6 $color[v] = color[v] + 1$
7 return color

Solution 87
Given an array $A$ of number, ALGO-X($A$) returns TRUE if and only if there are three numbers $x \leq y \leq z \in A$ such that $y - x = z - y$. ALGO-X does that by testing each triple of distinct elements of $A$. There are $\binom{n}{3} = n(n - 1)(n - 2)/3!$ such triples, so the complexity is $\Theta(n^3)$.

A better way to do the same thing is as follows:

Better-ALGO-X($A$)
1 sort $A$
2 for $i = 1$ to $A$.
3 for $j = i + 2$ to $A$.length
4 $m = (A[i] + A[j]) / 2$
5 if Binary-Search($A[i + 1 \ldots j - 1], m$)
6 return TRUE
7 return FALSE

In essence, after sorting the numbers, this algorithm tests each pair of non-adjacent numbers and then looks for the median using a binary search. There are $O(n^2)$ pairs of non-adjacent numbers in $A$, and binary-search costs $O(\log n)$, so the complexity is $O(n^2 \log n)$.

Solution 99
Is-Perfectly-Balanced($t$)
1 if $t$ == NIL
2 return (TRUE, 0)
3 ($balanced_l$, weight$_l$) = Is-Perfectly-Balanced($t$.left)
4 ($balanced_r$, weight$_r$) = Is-Perfectly-Balanced($t$.right)
5 if $balanced_l$ and $balanced_r$ and $|weight_r - weight_l| \leq 1$
6 return (TRUE, weight$_l$ + weight$_r$ + 1)
7 else return (FALSE, weight$_l$ + weight$_r$ + 1)

Solution 101
We are not allowed to modify $H$, and we are not allowed to create a copy of $H$ that we can then sort. So, we must print the elements in order, by simply reading $H$. We know that each number is unique in $H$, so the idea is this: we start from the minimum value in $H$, which happens to be in the first position of $H$, print that value, and then look for the second-smallest number, which we can simply find with a linear scan. We then proceed with the third-smallest, and so on, which again we can find with a linear scan. Notice that we can use a linear scan to find the $i$-th smallest element by simply considering only those elements in $H$ that are greater than the smallest element we found in the previous $(i - 1)$ scan.

In pseudo-code:

Heap-Print-In-Order($H$)
1 $m = H[0]$
2 print $m$
3 for $i = 2$ to $H$.length
4 $x = \infty$
5 for $j = 2$ to $H$.length
6 if $H[j] > m$ and $H[j] < x$
7 $x = H[j]$
8 $m = x$
9 print $m$
It is easy to see that the complexity of \textsc{Heap-Print-In-Order} is \( \Theta(n^2) \).

\textbf{Solution 105}

\textsc{Algo-X} removes every element equal to \( k \) from array \( A \) with a complexity of \( \Theta(n^2) \).

Consider as a worst-case input an array \( A \) in which all \( n \) values are equal to \( k \). In this case, \textsc{Algo-X} would iterate over lines 3 and 4 (always with \( i \) equal to 1). In each iteration, \textsc{Algo-X} would then invoke \textsc{Algo-Y} (again with \( i \) equal to 1), which would then iterate over the length of the array, effectively removing the \( i \)-th element by shifting every subsequent element to the left by 1 position, and then by cutting the length of the array by 1.

So, \textsc{Algo-Y} would run for \( n \) iterations the first time, then \( n - 1 \) the second time, then \( n - 2 \), and so on, until the array is completely empty. The complexity is therefore \( n + (n - 1) + \ldots + 2 + 1 = \Theta(n^2) \). A better way to remove every element equal to \( k \) from an array \( A \) is as follows.

\begin{verbatim}
 BETTER-ALGO-X(A,k)
 1  j = 1
 2  for i = 1 to A.length
 3      if A[i] ≠ k
 5         j = j + 1
 6  A.length = j - 1
\end{verbatim}

\textbf{Solution 136.2}

Optimal sequence: 32, 21, 25, 40, 37, 46, 41, 12, 23, 48, 14, 33, 38, 0, 28.

\textbf{Solution 140}

We can first start by modeling \textsc{Maximal-Non-Adjacent-Sequence-Weight} as a classic recursive dynamic-programming algorithm. Given a sequence \( A = a_1, a_2, \ldots, a_n \), there are two cases:

(i) the maximal sequence includes \( a_1 \), and therefore does not include \( a_2 \) and instead includes the maximal sequence for the remaining subsequence \( a_3 \ldots a_n \);

(ii) the maximal sequence does not include \( a_1 \) and therefore is the same as the maximal sequence for the subsequence starting at \( a_2 \).

Thus the maximal solution is the best of these two. Let \( OPT(a_1, a_2, \ldots, a_n) \) denote the maximal weight of non-adjacent elements from a sequence \( a_1, a_2, \ldots, a_n \). With this, the algorithm is as follows:

\[ OPT(a_1, a_2, a_3, \ldots, a_n) = \max\{a_1 + OPT(a_3, \ldots, a_n), OPT(a_2, \ldots, a_n)\} \]

Now we just have to write this simple, recursive dynamic-programming solution as a single iteration. This can be done by remembering only two values in each iteration, namely the optimal value for the previous two elements in the sequence. We can perform this iteration in either direction, so here we do it in increasing order, left-to-right. Therefore, for each element \( a_i \), we must remember
the two previous optimal values $OPT(a_1, \ldots, a_{i-1})$ and $OPT(a_1, \ldots, a_{i-2})$. The full algorithm is as follows:

**Maximal-Non-Adjacent-Sequence-Weight**($A$)

1. $p = 0$
2. $q = 0$
3. $r = 0$
4. For $i = 1$ to $A$.length
   5. $r = \max\{A[i] + p, q\}$
   6. $p = q$
   7. $q = r$
8. Return $r$

▷ Solution 155.1

min, max, min−1, max−1, min−2, max−2, ...

▷ Solution 155.2

Dynamic programming: with $i$ going from left to right, let $x(i)$ be the value of the maximal contiguous sequence ending at position $i$. So, $x(1) = A[1], x(i) = \max\{A[i] + x(i−1), A[i]\}.$

▷ Solution 163

**Max-Heap-Insert**($H, k$)

1. $H$.heap-size = $H$.heap-size + 1
2. $H[H$.heap-size] = $k$
3. $i = H$.heap-size
4. While $i > 1$ and $H[i] > H[[i/2]]$
   5. Swap $H[i] \leftrightarrow H[[i/2]]$
   6. $i = \left\lfloor i/2 \right\rfloor$

The complexity is $\Theta(\log n)$.

▷ Solution 164.1

**Find-Elements-At-Distance**($A, k$)

1. For $i = 1$ to $A$.length
   2. If Binary-Search($A[i + 1 \ldots A$.length], $k − A[i]$) return TRUE
   3. Return FALSE

The complexity is $\Theta(n\log n)$, since for each of the $n$ elements, we perform a binary search that runs in $\Theta(\log n)$.

▷ Solution 164.2

**Find-Elements-At-Distance**($A, k$)

1. $i = 1$
2. $j = 2$
3. While $j \leq A$.length
      5. $j = j + 1$
      7. $i = i + 1$
   8. Else return TRUE
9. Return FALSE

In each iteration of the loop we either increase $j$ or $i$ by one (or we return). Also, the loop is such that $j \geq i$, so in at most $\Theta(n)$ iterations we push $j$ beyond $A$.length. Thus the complexity is $\Theta(n)$. 
Solution 165

**Is-Prime** \((x)\)

1. \(i = 2\)
2. \(\textbf{while } i \cdot i < x\)
3. \(\textbf{if } i \text{ divides } x\)
4. \(\textbf{return } \text{TRUE}\)
5. \(i = i + 1\)
6. \(\textbf{return } \text{FALSE}\)

**Partition-Primes-Composites** \((A)\)

1. \(i = 1\)
2. \(j = 1\)
3. \(\textbf{while } i < j\)
4. \(\textbf{if } \text{Is-Prime}(A[j])\)
5. \(\text{swap } A[j] \leftrightarrow A[i]\)
6. \(i = i + 1\)
7. \(\textbf{elseif not } \text{Is-Prime}(A[i])\)
8. \(\text{swap } A[j] \leftrightarrow A[i]\)
9. \(j = j - 1\)
10. \(\textbf{else } i = i + 1\)
11. \(j = j - 1\)

**Is-Prime** runs in \(\Theta(\sqrt{m})\), while **Partition-Primes-Composites** requires \(\Theta(n)\) basic operations and \(\Theta(n)\) invocations of **Is-Prime**. The complexity is therefore \(\Theta(n \sqrt{m})\).

Solution 166

In this exercise, randomization or rotations cannot be used to balance the height of the BST. So, input sequence \(A\) must be pre-sorted so that, inserting elements in the tree in the new order, the resulting BST has still minimal height, \(O(\log n)\), even using the classic insertion algorithm (that could potentially result in unbalanced trees). Intuitively, this is possible by inserting elements in this order: \(\text{median}(1, n)\), \(\text{median}(1, \frac{n}{2})\), \(\text{median}(\frac{n}{2}, n)\), \(\text{median}(1, \frac{n}{4})\), \(\text{median}(\frac{n}{4}, \frac{n}{2})\), \(\text{median}(\frac{n}{2}, \frac{3n}{4})\), \(\text{median}(\frac{3n}{4}, n)\). Or, equivalently, \(\text{median}(1, n)\), \(\text{median}(1, \frac{n}{2})\), \(\text{median}(1, \frac{n}{4})\), \(\text{median}(\frac{n}{4}, \frac{n}{2})\), \(\text{median}(\frac{n}{2}, \frac{3n}{4})\), \(\text{median}(\frac{3n}{4}, n)\). The input array can be sorted in this order by using the functions below:

**Sort-For-Balanced-BST** \((A)\)

1. sort \(A\) in non-descending order
2. \(\textbf{Print-R}(A, 1, A.\text{length})\)

**Print-R** \((A, i, j)\)

1. \(\textbf{if } i \leq j\)
2. \(m = \lfloor (i + j)/2 \rfloor\)
3. \(\text{print } A[m]\)
4. \(\textbf{Print-R}(A, i, m - 1)\)
5. \(\textbf{Print-R}(A, m + 1, j)\)

**Print-R** runs in \(O(n)\), since it simply prints one element—the median element, since the input is sorted—and then recurses on the left and side parts by excluding the element it just printed. In the end, **Print-R** runs (recursively) exactly once for each element of the array. So, the complexity of **Print-R** is \(O(n)\) and the dominating cost for **Sort-For-Balanced-BST** is the cost of sorting, which can be done in \(O(n \log n)\).

Solution 167.1

**Minimal-Simplified-Sequence** \((A)\)

1. \(X = \emptyset\)
2. sort \(A\) in non-decreasing order
3. \(\textbf{for } i = A.\text{length} \textbf{ downto } 3\)
4. \(\textbf{for } j = A.\text{length} \textbf{ downto } 3\)
5. \(\textbf{if } \text{Binary-Search}(A[1\ldots j - 1], A[i] - A[j]) \neq \text{FALSE}\)
6. \(X = X \cup \{A[i]\}\)
7. \(\textbf{return } X\)

Hey, is the solutions above incorrect? An alternative solution is below:
Minimal-Simplified-Sequence\(A\)

1. \(X = \emptyset\)
2. sort \(A\) in non-decreasing order
3. for \(i = 1\) to \(A.\text{length} - 1\)
   4. for \(j = i + 1\) to \(A.\text{length}\)
      5. \(i = \text{Binary-Search}(A[j + 1...A.\text{length}], A[i] + A[j])\)
      6. if \(i > 0\)
         7. \(X = X \cup \{A[i]\}\)
   8. return \(X\)

The complexity is \(\Theta(n^2 \log n)\).

Solution 167.2

Minimal-Simplified-Sequence\(A\)

1. \(B = \text{array of } A.\text{length} \text{ zeroes}\)
2. sort \(A\) in non-decreasing order
3. for \(i = 1\) to \(A.\text{length} - 2\)
   4. \(j = i + 1\)
   5. \(k = i + 2\)
   6. while \(k \leq A.\text{length}\)
         8. \(k = k + 1\)
         10. \(j = j + 1\)
      11. else
          12. \(B[k] = 1\)
       13. \(k = k + 1\)
14. for \(i = 1\) to \(A.\text{length}\)
15. if \(B[i] == 0\)
16. \(X = X \cup \{A[i]\}\)
17. return \(X\)

Solution 168

The algorithm consists of two nested loops. The outer loop takes variable \(a\) from \(n\) to 1 by dividing \(a\) in half at every iteration. Therefore, the values of \(a\) are \(n, n/2, n/4, n/8\ldots\). That is, at iteration \(i\) of the outer loop, \(a = n/2^i\). The outer loop terminates when \(n/2^i \leq 1\), that is, it runs for \(\lceil \log n \rceil\) iterations.

The inner loop takes variable \(b\) from 1 to \(a^2\) by doubling \(b\) at every iteration. Therefore the values of \(b\) are 1, 2, 4, \ldots, that is, \(b = 2^j\) at the \(j\)-th iteration of the inner loop. Therefore the inner loop runs for \(2 \log a\) iterations.

Altogether, the complexity is

\[
T(n) = \sum_{i=1}^{\lceil \log n \rceil} 2 \log(n/2^i)
\]

\[= \Theta(\log^2 n).\]
Solution 169

FIND-CYCLE\((G)\)

1. \(N = \text{array of size } |V(G)| \) // visited
2. \(P = \text{array of size } |V(G)| \) // previous
3. for \(v \in V(G)\)
4. \(N[v] = \text{false}\)
5. \(P[v] = \text{null}\)
6. for \(v \in V(G)\)
7. if not \(N[v]\)
8. \(N[v] = \text{true}\)
9. \(P[v] = v\)
10. return \(true\)
11. return \(false\)

FIND-CYCLE-R\((N, P, v)\)

1. for \(w \in v.\text{Adj}\)
2. if \(N[w]\)
3. \(u = P[v]\)
4. while \(u \neq \text{null}\)
5. if \(u == w\)
6. \(N[w] = \text{true}\)
7. \(u = P[u]\)
8. else \(P[w] = v\)
9. if FIND-CYCLE-R\((N, P, w)\)
10. \(return \text{true}\)
11. \(return \text{false}\)

Solution 170.1

BFS-FIRST-COMMON-ANCESTOR\((\pi, u, v)\)

1. \(S = \text{array of size } |\pi|\)
2. for \(i = 1\) to \(|\pi|\)
3. \(S[i] = 0\)
4. while \(u \neq \text{null} \text{ or } v \neq \text{null}\)
5. if \(u \neq \text{null}\)
6. if \(S[u] = 1\)
7. \(\text{return } u\)
8. else \(u = \pi[u]\)
9. \(\text{return } v\)
10. if \(v \neq \text{null}\)
11. if \(S[v] = 1\)
12. \(v = \pi[v]\)
13. \(\text{return } \text{null}\)

The time complexity is \(\Theta(n)\). The space complexity is \(\Theta(n)\).

Solution 170.2

BFS-FIRST-COMMON-ANCESTOR-2\((\pi, D, u, v)\)

1. if \(D[u] == \infty\ \text{or } D[v] == \infty\)
2. \(\text{return } \text{null}\)
3. while \(u \neq v\)
4. if \(D[u] < D[v]\)
5. \(u = \pi[u]\)
6. else \(v = \pi[v]\)
7. \(\text{return } u\)

The time complexity is \(\Theta(n)\).
Solution 172.1

BST-Find-Sum(T, v)
1 \( t_1 = \text{BST-Min}(T) \)
2 \( \text{while } t_1 \neq \text{NULL} \)
3 \( t_2 = \text{BST-Search}(T, v - t.\text{key}) \)
4 \( \text{if } t_2 \neq \text{NULL} \)
5 \( \text{return } t_1, t_2 \)
6 \( \text{else} \)
7 \( \text{else } t_1 = \text{BST-Successor}(t_1) \)
8 \( \text{return } \text{NULL} \)

The time complexity is \( \Theta(n^2) \).

Solution 172.2

BST-Lower-Bound(t, v)
1 \( \text{// rightmost element whose key is } \leq v, \text{ or } \text{NULL} \)
2 \( \text{while } t \neq \text{NULL} \)
3 \( \text{if } v < t.\text{key} \)
4 \( t = t.\text{left} \)
5 \( \text{elseif } t.\text{right} \neq \text{NULL} \text{ and } t.\text{right.key} < v \)
6 \( t = t.\text{right} \)
7 \( \text{else return } t \)
8 \( \text{return } \text{NULL} \)

BST-Find-Sum(T, v)
1 \( t_1 = \text{BST-Lower-Bound}(T, v/2) \)
2 \( t_2 = \text{BST-Successor}(t_1) \)
3 \( \text{while } t_1 \neq \text{NULL} \text{ and } t_2 \neq \text{NULL} \)
4 \( \text{if } t_1 + t_2 = v \)
5 \( \text{return } t_1, t_2 \)
6 \( \text{elseif } t_1 + t_2 < v \)
7 \( t_2 = \text{BST-Successor}(t_2) \)
8 \( \text{else } t_1 = \text{BST-Predecessor}(t_1) \)
9 \( \text{return } \text{NULL} \)

The time complexity is \( \Theta(n) \).

Solution 173.1

Verify-K-Pairwise-Relatively-Prime(X, k, S)
1 \( \text{GCD}(a, b) \)
2 \( \text{ while } a \neq b \)
3 \( \text{ if } a > b \)
4 \( a = a \% b \)
5 \( \text{else } b = b \% a \)
6 \( \text{return } a \)
7 \( \text{return } \text{TRUE} \)

The time complexity is \( O(k \log n + k^2 \log m) \), where \( m \) is the maximum value in \( X \).

Solution 181

Minimal-Covering-Square($P$)

1. if $P$.length == 0
   2. return 0
3. left = $P[1].x$
4. right = $P[1].x$
5. top = $P[1].y$
6. bottom = $P[1].y$
7. for i = 2 to $P$.length
   8. if $P[i].x > right$
      9. right = $P[i].x$
   10. elseif $P[i].x < left$
      11. left = $P[i].x$
   12. if $P[i].y > top$
      13. top = $P[i].y$
   14. elseif $P[i].y < bottom$
      15. bottom = $P[i].y$
   16. if right - left > top - bottom
      17. return $(right - left)^2$
   18. else return $(top - bottom)^2$

Solution 182

Unimodal-Find-Maximum($A$)

1. $l = 1$
2. $h = A$.length
3. while $l < h - 1$
   4. $m = \lfloor (l + h)/2 \rfloor$
   5. if $A[m - 1] > A[m]$
      6. $h = m$
   7. elseif $A[m + 1] > A[m]$
      8. $l = m$
   9. else return $A[m]$
10. error "A is not a unimodal sequence"

Solution 183.1

Better-Algo-X($A, k$) returns the beginning and ending position of a minimal subsequence of $A$ that contains at least $k$ equal elements. The complexity of Better-Algo-X is $\Theta(n^4)$. In essence, this is because there are four nested loops.
Solution 183.2

Notice that any minimal sequence \( P[i], P[i+1], \ldots, P[j] \) that contains at least \( k \) equal elements contains exactly \( k \) elements equal to the first and last element of the sequence. Otherwise, \( P[i], \ldots, P[j-1] \) would be a smaller sequence that still contains at least \( k \) equal elements.

So, we just have to find a sequence that starts and ends with the same element \( x \), and contains exactly \( k \) elements equal to \( x \), including the first and last element:

\[
\text{Better-Algo-X}(A, k)
\]

1. \( l = -\infty \)
2. \( r = +\infty \)
3. \textbf{for} \( i = 1 \) \textbf{to} \( A.\text{length} \)
4. \( c = 1 \)
5. \( j = i + 1 \)
6. \textbf{while} \( c < k \) \textbf{and} \( j \leq \text{min}(A.\text{length}, i + r - l) \)
8. \( c = c + 1 \)
9. \( j = j + 1 \)
10. \textbf{if} \( c == k \) \textbf{and} \( r - l > j - i \)
11. \( l = i \)
12. \( r = j \)
13. \textbf{return} \( l, r \)

The complexity of \text{Better-Algo-X} is \( O(n^2) \).

Solution 184.1

\text{Three-Way-Partition}(A, \text{begin}, \text{end})

1. \( q_1 = \text{begin} \)
2. \( q_2 = q_1 + 1 \)
3. \textbf{for} \( i = q_1 + 1 \) \textbf{to} \( \text{end} - 1 \)
4. \textbf{if} \( A[i] \leq A[q_1] \)
5. \( \text{swap } A[i] \leftrightarrow A[q_2] \)
7. \( \text{swap } A[q_2] \leftrightarrow A[q_1] \)
8. \( q_1 = q_1 + 1 \)
9. \( q_2 = q_2 + 1 \)
10. \textbf{return} \( q_1, q_2 \)

Solution 184.2

\text{Quick-Sort}(A)

1. \text{Quick-Sort-R}(A, 1, A.\text{length} + 1)

\text{Quick-Sort-R}(A, \text{begin}, \text{end})

1. \textbf{if} \( \text{begin} < \text{end} \)
2. \( q_1, q_2 = \text{Three-Way-Partition}(A, \text{begin}, \text{end}) \)
3. \text{Quick-Sort-R}(A, \text{begin}, q_1) \)
4. \text{Quick-Sort-R}(A, q_2, \text{end})

This variant would be much more efficient with sequences often-repeated elements. In the extreme case of a sequence with \( n \) identical numbers, this variant would terminate in time \( O(n) \), while the classic algorithm would run in time \( O(n^2) \).

Solution 185

\( S(A, s) \) returns \text{TRUE} if there is a subset of the elements in \( A \) that add up to \( s \). This is also known as the \text{subset-sum} problem.

The best-case complexity is \( O(n) \). An example of a best-case input (of size \( n \)) is with any array \( A \) and with \( s = 0 \). In this case, the algorithm recurses \( n \) times in line 3, only then to return \text{TRUE} from line 2 of the last recursion, and then unrolling all the recursions out of line 3 to ultimately return \text{TRUE} out of line 4.

The worst-case complexity is \( O(2^n) \). A worst-case input (of size \( n \)) is one that leads to a \text{FALSE} result. An example would be an array \( A \) of positive numbers with \( s < 0 \). In this case, every
Each invocation recurses twice, except for the base case. Each recursion reduces the size of the input range by 1, so the recursion tree amounts to a full binary tree with $n$ levels, which leads to a complexity of $O(2^n)$.

**Solution 186**

GROUP-OF-K($S_1, S_2, \ldots, S_m, k$)
1. $H = \text{empty min-heap (sorted by time)}$
2. for $i = 1$ to $m$
   3. $t, a = S_i[1]$
   4. MIN-HEAP-INSERT($H, (t, a, i, 1)$) (sorted by $t$)
5. $C = \text{dictionary mapping antennas to integers (hash map)}$
6. while $H$ is not empty
   7. $t, a, i, j = \text{MIN-HEAP-EXTRACT-MIN}(H)$ (sorted by $t$)
   8. if $j > 1$
      9. $t', a' = S_i[j - 1]$
     10. $C[a'] = C[a'] - 1$
   11. if $a \in C$
      12. $C[a] = C[a] + 1$
   13. else $C[a] = 1$
   14. if $C[a] \geq k$
      15. return $t, a$
   16. if $j \leq S_i.\text{length}$
      17. $t, a = S_i[j + 1]$
     18. MIN-HEAP-INSERT($H, (t, a, i, j + 1)$) (sorted by $t$)
   19. return NULL

**Solution 187.1**

ALGO-X($A$) sorts the elements of $A$ in-place so that all odd numbers precede all even numbers. In other words, ALGO-X($A$) partitions $A$ in two parts, $A[1 \ldots j - 1]$ and $A[j \ldots A.\text{length}]$ so that $A[1 \ldots j - 1]$ contains only odd numbers and $A[j \ldots A.\text{length}]$ contains only even numbers. One of the two parts might be empty. The complexity of ALGO-X is $\Theta(n^2)$.

**Solution 187.2**

BETTER-ALGO-X($A$)
1. $i = 1$
2. $j = A.\text{length} + 1$
3. while $i < j$
   4. if $A[i] \equiv 0 \mod 2$ // $A[i]$ is even
      5. $j = j - 1$
   6. swap $A[i] \leftrightarrow A[j]$
   7. else $i = i + 1$
4. return $j$

**Solution 188**

BTree-Print-Range($T, a, b$)
1. if not $T.\text{leaf}$ and $T.\text{key}[1] > a$
2. BTree-Print-Range($T.\text{c}[1], a, b$)
3. for $i = 1$ to $T.\text{n}$
   4. if $T.\text{key}[i] \geq b$
      5. return
   6. if $T.\text{key}[i] > a$
      7. print $T.\text{key}[i]$
   8. if not $T.\text{leaf}$
      9. if $i == T.\text{n}$ or $T.\text{key}[i + 1] > a$
         10. BTree-Print-Range($T.\text{c}[i + 1], a, b$)
Solution 189
The problem is in P, and therefore it is also in NP. This is a polynomial-time solution algorithm that proves it:

\[ \text{ALGO}(G, k) \]
1. for \( v \in V(G) \)
2. \( D_v = \text{DIJKSTRA}(G, v) \)
3. // \( D_v \) is the distance vector resulting from Dijkstra
4. for \( u \in V(G) \)
5. if \( D_v[u] = k \)
6. return TRUE
7. return FALSE

Solution 190
MOST-CONGESTED-SEGMENT\((A, \ell)\)
1. sort \( A \)
2. \( i = 1 \)
3. \( j = 1 \)
4. \( x = \text{NULL} \)
5. \( m = 0 \)
6. while \( j < A.\text{length} \)
7. if \( A[j] - A[i] \leq \ell \)
8. if \( m < j - i + 1 \)
9. \( x = A[i] \)
10. \( m = j - i + 1 \)
11. \( j = j + 1 \)
12. else \( i = i + 1 \)
13. return \( x \)

Solution 191
The problem is in NP because a true answer can be verified in polynomial time with a "certificate" consisting of a set of nodes \( C = \{v_1, v_2, \ldots, v_\ell\} \)

\[ \text{VERIFY}(G, k, C = \{v_1, v_2, \ldots, v_\ell\}) \]
1. if \( |C| < k \)
2. return FALSE
3. for all pairs \( u, v \in C \)
4. if \( G[u][v] \neq 1 \)
5. return FALSE
6. return TRUE

Solution 192
MAX-HEAP-TOP-THREE\((H)\)
1. if \( H.\text{length} < 4 \)
2. for \( i = 1 \) to \( H.\text{length} \)
3. else print\((H[1])\)
5. \( i = 2 \)
6. \( j = 3 \)
7. else \( i = 3 \)
8. \( j = 2 \)
9. if \( H.\text{length} \geq 2i + 1 \) and \( H[j] < H[2i + 1] \)
10. \( j = 2i + 1 \)
11. if \( H.\text{length} \geq 2i \) and \( H[j] < H[2i] \)
12. \( j = 2i \)
13. print\((H[i])\)
14. print\((H[j])\)
\textbf{Solution 193}

\textbf{LONGEST-STRETCH}(P, h)
\begin{verbatim}
1    ℓ = 0
2    i = 1
3    while i < P.length
4       a = P[i].y
5       b = P[i].y
6       j = i + 1
7       while b - a < h
8          if P[j].y > b
9              b = P[j].y
10             elseif P[j].y < a
11                a = P[j].y
12                if b - a < h
13                    if P[j].x - P[i].x > ℓ
14                        ℓ = P[j].x - P[i].x
15                    else j = j + 1
16            i = i + 1
17    return ℓ
\end{verbatim}

\textbf{LONGEST-STRETCH}(P, h) runs in } O(n^2) \text{ in the worst case. For example, a completely flat road would be a worst-case input.}

\textbf{Solution 194}

\textbf{IS-BIPARTITE}(G)
\begin{verbatim}
1    for v ∈ V(G)
2       C[ ] = GREEN // can be in either V_A or V_B
3    for v ∈ V(G)
4       if C[v] == GREEN
5          C[v] = RED
6          Q = {v} // queue containing v
7          while Q is not empty
8             u = DEQUEUE(Q)
9              for all w adjacent to u:
10                 if C[w] == GREEN
11                    if C[v] == RED
12                        C[w] = BLUE
13                    else C[w] = RED
14                     ENQUEUE(Q, w)
15                 else if C[v] ≠ C[w]
16                     return FALSE
17    return TRUE
\end{verbatim}

\textbf{Solution 195.1}

\textbf{GOOD-ARE-ADJACENT}(A)
\begin{verbatim}
1    i = 1
2    while i < j and not IS-GOOD(A[i])
3       i = i + 1
4    while i < j and not IS-GOOD(A[j])
5       j = j - 1
6    while i < j
7       if not IS-GOOD(A[i])
8          else i = i + 1
9    return TRUE
\end{verbatim}
Solution 195.2

MAKE-GOOD-ADJACENT(A)
1  i = 1
2  while i < j and not IS-GOOD(A[i])
3     i = i + 1
4  while i < j and not IS-GOOD(A[j])
5     j = j - 1
6  while i < j
7     if not IS-GOOD(A[i])
9     j = j - 1
10    i = i + 1
11  return true

Solution 196

The problem is in P, and therefore also in NP. This is an algorithm that solves the problem in $O(n \log n)$ time.

GROUP-OF-EQUALS(A, k)
1  B = SORT(A)
2  i = 1
3  j = 1
4  while j < A.length
5    if A[i] == A[j]
6       j = j + 1
7    if j - i == k
8       return true
9  else i = j
10  return false

Solution 197

A simple, brute-force solution is to check each combination of positions in the two strings

MAXIMAL-COMMON-SUBSTRING(X, Y)
1  m = 0
2  for i = 1 to A.length
3     for j = 1 to B.length
4       ℓ = 0
5       while i + ℓ ≤ A.length and j + ℓ ≤ B.length and A[i + ℓ] == B[j + ℓ]
6         ℓ = ℓ + 1
7      if ℓ > m
8         m = ℓ
9  return m

The complexity of MAXIMAL-COMMON-SUBSTRING is $O(n^3)$.

Solution 198

BST-COUNT-UNBALANCED-NODES(t)
1  if t == NULL
2     return 0, 0
3  U_L, Tot_L = BST-COUNT-UNBALANCED-NODES(t.left)
4  U_R, Tot_R = BST-COUNT-UNBALANCED-NODES(t.right)
5  U = U_L + U_R
6  if Tot_L > 2Tot_R + 1 or Tot_R > 2Tot_L + 1
7     U = U + 1
8  return U, (Tot_L + Tot_R + 1)

The complexity is $\Theta(n)$. 
Solution 199.1

Algo-X returns the maximal difference between two values in an increasing sequence of elements in A. The complexity is $\Theta(n^3)$.

Solution 199.2

Linear-Algo-X(A)

1. \( x = 0 \)
2. \( i = 0 \)
3. \( j = 1 \)
4. while \( j \leq A.length \)
6. \( \text{if } A[j] - A[i] > x \)
8. else \( i = j \)
9. \( j = j + 1 \)
10. return \( x \)

Solution 200.1

A naïve solution for Find-Square is to test all quadruples of points \( p_i, p_j, p_k, p_\ell \), and determine whether \( p_i, p_j, p_k, p_\ell \) form a square.

Find-Square(P)

1. for \( i = 1 \) to \( P.length \)
2. \( \text{for } j = 1 \) to \( P.length \)
3. \( \text{for } k = 1 \) to \( P.length \)
4. \( \text{for } \ell = 1 \) to \( P.length \)
5. \( d_x = P[j].x - P[i].x \)
6. \( d_y = P[j].y - P[i].y \)
7. if \( P[k].x == P[j].x + d_y \) and \( P[k].y == P[j].y - d_x \)
   and \( P[\ell].x == P[i].x + d_y \) and \( P[\ell].y == P[i].y - d_x \)
8. return \( \text{true} \)
9. return \( \text{false} \)

Solution 200.2

Here the idea is to test all segments defined by two distinct points, and then to try to find the other corners of a square, which we can do with a binary search.

Order-2D(p_1, p_2)

1. if \( p_1.x < p_2.x \)
2. return \( \text{true} \)
3. elseif \( p_1.x > p_2.x \)
4. return \( \text{false} \)
5. elseif \( p_1.y < p_2.y \)
6. return \( \text{true} \)
7. elseif \( p_1.y < p_2.y \)
8. else return \( \text{false} \)

Binary-Search-2D(P, x, y)

1. \( i = 1 \)
2. \( j = P.length \)
3. \( \text{while } i \leq j \)
4. \( m = \lfloor (i + j)/2 \rfloor \)
5. if Order-2D(v, P[m])
6. \( j = m - 1 \)
7. elseif \( P[m].x == x \) and \( P[m].y == y \)
8. return \( \text{true} \)
9. else \( i = m + 1 \)
10. return \( \text{false} \)
**Solution 201**

**Enqueue(Q, obj, p)**

1. append obj to array Q.A
2. append p to array Q.P
3. i = Q.P.length
4. j = \(\lfloor i/2 \rfloor \)
5. while i > 1 and Q.P[i] < Q.P[j]
6. swap Q.P[i] ↔ Q.P[j]
8. i = j
9. j = \(\lfloor i/2 \rfloor \)

**Dequeue(Q)**

1. \(\ell = A.P.length\)
2. if \(\ell < 1\)
3. error "empty queue"
4. \(x = Q.A[1]\)
5. swap Q.P[1] = Q.P[\(\ell\)]
7. remove last element from Q.P
8. remove last element from Q.A
9. \(\ell = \ell - 1\)
10. i = 1
11. while \(2i \leq \ell \) and Q.P[i] > Q.P[2i]
     or \(2i + 1 \leq \ell \) and Q.P[i] > Q.P[2i + 1]
12. if \(2i + 1 \leq \ell \) and Q.P[2i + 1] > Q.P[2i]
13. \(j = 2i + 1\)
14. else \(j = 2i\)
15. swap Q.P[i] = Q.P[j]
17. i = j
18. return \(x\)

**Maximal-Distance(A)**

1. if A.length < 2
2. return 0
3. min = A[1]
4. max = A[1]
5. for i = 2 to A.length
6. if A[i] > max
7. max = A[i]
8. elseif A[i] < min
9. min = A[i]
10. return max - min

**Solution 202**

**Find-Square(P)**

1. sort \(P\) using ORDER-D as a comparison between pairs of points
2. for \(i = 1\) to \(P.length\)
3. for \(j = 1\) to \(P.length\)
4. \(d_x = P[j].x - P[i].x\)
5. \(d_y = P[j].y - P[i].y\)
6. if BINARY-SEARCH-2D(P, \(P[i].x + d_y, P[i].y - d_x\))
   and BINARY-SEARCH-2D(P, \(P[j].x + d_y, P[j].y - d_x\))
7. return TRUE
8. return FALSE

**Initialize(Q)**

1. Q.A = new empty array
2. Q.P = new empty array

**Enqueue(Q, obj, p)**

1. append obj to array Q.A
2. append p to array Q.P
3. i = Q.P.length
4. j = \(\lfloor i/2 \rfloor \)
5. while \(i > 1\) and Q.P[i] < Q.P[j]
6. swap Q.P[i] ↔ Q.P[j]
8. i = j
9. j = \(\lfloor i/2 \rfloor \)
Solution 203

\[
\text{BST-Height}(t) \begin{align*}
1 & \text{if } t = \text{null} \\
2 & \quad \text{return } 0 \\
3 & \text{return } 1 + \max(\text{BST-Height}(t.\text{left}), \text{BST-Height}(t.\text{right}))
\end{align*}
\]

Solution 204

The problem, which is the well-known matching problem in graph theory, is definitely in \(\text{NP}\). This is a possible verification algorithm:

\[
\text{Verify-Matching}(G = (V, E, w), t, S) \begin{align*}
1 & X = \emptyset \\
2 & \text{for } e = (u, v) \in S \\
3 & \quad \text{if } u \in X \text{ or } v \in X \\
4 & \quad \quad \text{return } \text{FALSE} \\
5 & \quad X = X \cup \{u, v\} \\
6 & \quad \text{weight} = \text{weight} + w(e) \\
7 & \quad \text{if } \text{weight} \geq t \\
8 & \quad \quad \text{return } \text{TRUE} \\
9 & \quad \text{else return } \text{FALSE}
\end{align*}
\]

Solution 205

We can use a dynamic programming approach. Let \(P_i\) be the maximal value of the objects you can collect by reaching object \(i\). Now, since you can reach \(P_i\) only by increasing your \(x\) and \(y\) coordinates, then that means that the maximal total value \(P_i\) is the value of object \(i\) plus the maximal total value when you reach any one of the objects from which you can then reach object \(i\). This means all the objects with coordinates less than those of \(i\). So:

\[
P_i = V[i] + \max_{j | X[j] \leq X[i] \land Y[j] \leq Y[i]} P[j]
\]

The global maximal game value is then \(\max P_i\).

Now, the formula for \(P_i\) gives us a very simple recursive algorithm. This is inefficient, but it can be made very efficient with memoization.

\[
\text{Maximal-Game-Value}(X, Y, V) \begin{align*}
1 & P = \text{array of } n = |V| \text{ elements initialized to } P[i] = \text{null} \\
2 & m = -\infty \\
3 & \text{for } i = 1 \text{ to } V.\text{length} \\
4 & \quad \text{if } m < \text{Maximal-Value-P}(P, X, Y, V, i) \\
5 & \quad m = \text{Maximal-Value-P}(P, X, Y, V, i) \\
6 & \text{return } m
\end{align*}
\]

\[
\text{Maximal-Value-P}(P, X, Y, V, i) \begin{align*}
1 & \text{if } P[i] = \text{null} \\
2 & P[i] = V[i] \\
3 & \text{for } j = 1 \text{ to } V.\text{length} \\
4 & \quad \text{if } j \neq i \text{ and } X[j] \leq X[i] \text{ and } Y[j] \leq Y[i] \\
5 & \quad \quad \text{if } P[i] < V[i] + \text{Maximal-Value-P}(P, X, Y, V, j) \\
6 & \quad \quad P[i] = V[i] + \text{Maximal-Value-P}(P, X, Y, V, j)
\end{align*}
\]

Solution 206

We are not required to be particularly efficient, so we can write a simple algorithm.
Maximal-Substring(S)
1  A = NULL
2  for i = 1 to |S|
3      X = ∅
4      for j = 1 to |S[i]| - 1
5          for k = j + 1 to |S[i]|
6              X = X ∪ {S[i][j...k]}
7      if A == NULL
8          A = X
9      else A = A ∩ X
10     if A == ∅
11        return ""
12  return longest string in A or "" if A == NULL.

Solution 207.1
ALGO-X returns mode of A, meaning an element that occurs in A with maximal frequency (count). The complexity is Θ(n^2). Any input is the worst-case input.

Solution 207.2
BETTER-ALGO-X(A)
1  B = copy of A
2  sort B
3  if |S| == 0
4      return 0
5  x = B[1]
6  m = 1
7  c = 1
8  for i = 2 to |S|
9      if B[i] == B[i - 1]
10         c = c + 1
11      if c > m
12         m = c
13         x = B[i]
14      else c = 1
15  return x

Solution 208
GRAPH-DEGREE(G)
1  n = |V(G)|
2  for i = 1 to n
3      d = 0
4      for j = 1 to n
5          if G[i,j] == 1
6              d = d + 1
7      if d > m
8          m = d
9  return m

Solution 209
We don’t have complexity constraints, so the algorithm can be simple:
**Solution 210**

Here's an obvious $O(mn^2)$ solution:

```plaintext
LONGEST-COMMON-PREFIX(S)
1 m = 0
2 for i = 2 to S.length
3   for j = 1 to i - 1
4     ℓ = COMMON-PREFIX-LENGTH(S[i], S[j])
5     if ℓ > m
6        ℓ = m
7 return m
```

**Solution 211**

Notice that if we sort the array $S$ in lexicographical order, then any $k$ strings with a common prefix will be contiguous in the sorted array.

```plaintext
LONGEST-K-COMMON-PREFIX(S, k)
1 sort S in lexicographical order
2 m = 0
3 for i = k to S.length
4   ℓ = COMMON-PREFIX-LENGTH(S[i], S[i - k])
5   if ℓ > m
6      ℓ = m
7 return m
```

This complexity is $O(m \log n)$.

**Solution 212**

The problem is in $P$ and therefore it is also in $NP$. This is an algorithm that solves the problem in polynomial time:

```plaintext
NEGATIVE-THREE-CYCLE(G = (V, E))
1 for u ∈ V
2   for v ∈ Adj[u]
3     for w ∈ Adj[v]
4       if w = u and weight(u, v) + weight(v, w) + weight(w, u) < 0
5          return TRUE
6 return FALSE
```
Solution 213.1

```plaintext
UPPER-BOUND(A, x)
1  u = UNDEFINED
2  d = UNDEFINED
3  for a ∈ A
4      if x ≤ a
5          if u == UNDEFINED or d > a − x
6          d = a − x
7          u = a
8  return u
```

The complexity is $\Theta(n)$.

Solution 213.2

```plaintext
UPPER-BOUND-SORTED(A, x)
1  i = 1
2  j = A.length
3  if A[j] < x
4      return UNDEFINED
5  elseif A[i] ≥ x
6      return A[i]
7  while i < j
8      m = ⌊i + j/2⌋
9      if A[m] == x
10     return A[m]
11  elseif A[m] < x
12      i = m
13  else j = m
14  return A[j]
```

The complexity is $\Theta(\log n)$.

Solution 213.3

```plaintext
UPPER-BOUND-BST(T, x)
1  while T ≠ NULL
2      if T.key < x
3          T = T.right
4      else while T.left ≠ NULL and T.left.key ≥ x
5          T = T.left
6  return T.key
7  return UNDEFINED
```

The complexity is $\Theta(h)$ where $h$ is the height of the input tree.
